SERVING FARMERS AND SAVING FARMING

FIRST REPORT

NATIONAL COMMISSION ON FARMERS
MINISTRY OF AGRICULTURE
GOVERNMENT OF INDIA, NEW DELHI
DECEMBER 2004
EXECUTIVE SUMMARY

CHAPTER I - WAKE-UP CALL

The acute agricultural distress now witnessed in the country, occasionally taking the form of suicides by farmers, is the symptom of a deep seated malady arising from inadequate public investment and insufficient public action in recent years. The precise causes of the agrarian crisis are many and varied, but there are five basic factors which are central to the present crises. These are: unfinished agenda in land reform, quantity and quality of water, technology fatigue, access, adequacy and timeliness of institutional credit, and opportunities for assured and remunerative marketing. Adverse meteorological factors add to these problems. The worst affected are small and marginal farmers, tenants and share croppers, landless agricultural labour and tribal farmers, since their coping capacity is very limited. Women suffer more since they have little access to institutional credit or organised extension support.

2. The ecological foundations of sustainable agriculture such as land, water, biodiversity, forests and the atmosphere are under varying degrees of anthropogenic pressures. Water tables are going down and land degradation and soil salinisation are on the rise. Average size of farm holdings is declining and there are now nearly 115 million farmers, most of them belonging to the small and marginal farmer categories. Farmers' indebtedness is growing even in a State like the Punjab, which is the heartland of the green revolution.

3. State governments have an equal responsibility for ensuring that adequate and appropriate support is extended to the farm sector, comprising crop and animal husbandry, forestry, fisheries and agro-processing and agri-business. Even if there are good schemes which can be of real help to farm women and men, their delivery is poor. Illiterate farm women and men are also often unaware of their entitlements. An urgent need at the field level is achieving convergence and synergy among all on-going programmes. It is therefore suggested that the numerous Technology Missions currently
under implementation, such as the ones dealing with oilseeds, pulses, maize and millets, cotton, horticulture and Dairy may converge on a watershed basis, so that the water harvested and saved in the watershed is put to optimum use. To facilitate such convergence in delivery, we suggest the formation of a National Federation of Farm Technology Missions chaired by a farm woman or man, with an outstanding record of practical achievement.

4. Small farm families will have to be conferred with the power of scale at the production and post-harvest phases. Different institutional devices like the formation of self-help groups (SHGs), contract farming based on a code of conduct, group farming through small Farmers' Cotton, Horticulture and Poultry Estates, and the nurturing of watershed and command area communities, will have to be adopted according to local socio-cultural and agro-economic conditions. There is also a need for a New Deal for Women in Agriculture, in order to ensure that working women have the needed support services and have access to timely credit and extension services.

5. The two pronged strategy to resource mobilization consists of optimizing the benefits of all Government schemes and reducing their transaction costs, and optimizing the return from the resource endowments of farmers like land, livestock and water. The additional funds needed will be for filling critical gaps in current public investments and programmes.

6. Irrigation water is becoming a critical constraint in agriculture. In the Union budget of 2004-05, provision has been made to launch a massive scheme to retain, renovate and restore all the water bodies that are linked to agriculture. The following two programmes are suggested for taking this movement forward.

   i) A million well recharge programme

   ii) A programme for building, repair, recharging and rebuilding water bodies linked to agriculture.

   iii) There is need for a mandatory water harvesting regulation as is already in practice in Tamil Nadu. Government support for the Million Wells and
water bodies rehabilitation programmes could be in the form of a rebate on agricultural credit.

7. Besides the quantity and quality of irrigation water available, soil health influences output. Soils, particularly in dry farming areas, suffer from hidden hunger caused by the deficiency of micronutrients. Soil testing laboratories need to be upgraded. Hence, a National Network of Advanced Soil Testing Laboratories is recommended. Also, farmers need proactive advice on land use. Computerised databases need to be developed by multidisciplinary teams of experts. Such data can be transmitted to farming families through the Village Knowledge Centre programme.

8. In the midst of the hunger and distress “hot spots”, there are numerous agricultural “bright spots” in the country. The ‘bright spots’ covering crops, fruits trees, farm animals and fisheries indicate how we can shape our agricultural future. These bright spots are the result of the work of innovative and hard working farm women and men. It is suggested that Farm Schools may be established in the fields of such innovative farmers, in order to spread their message and methods. A cadre of grass root Master Trainers can be built up in such Farm Schools. Farm schools can also be powerful instruments for participatory research and knowledge management. Thus, starting with Farm Schools in working farmers’ fields, there will be a chain of capacity building institutions including KVKs and Agricultural Universities. Promoting 50,000 Farm Schools across the country will require an investment of Rs.150 crore.

9. The 150 districts chosen for the launch of the Food for Work and Employment Guarantee Schemes require considerable support from S & T institutions for fostering sustainable livelihoods, through integrated attention to on-farm and skilled non-farm employment. In order to facilitate multi-institutional and multi-disciplinary support for launching a job-led economic growth strategy, it is proposed that a National S&T Alliance for Rural Livelihood Security may be formed in consultation with national S&T institutions, Agricultural and Rural Universities, Civil Society and private sector industrial institutions and with counterpart structures in the States taken up for the initial Food for Work programme. An appropriate State Agricultural University may service
the State level S & T Alliance, while at the District level, the Alliance partners may work with DRDA. The aim of this partnership among public, private and academic sector S & T institutions is the technological and skill empowerment of assetless rural women and men in order to add economic value to their time and labour. If technology has been a factor in widening the rich-poor divide in the past, **the National S & T Alliance will strive to make technology an ally in the movement for gender and social equity.**

10. Our agriculture is at the crossroads economically, environmentally, socially and technologically. To reverse the present decline in farm productivity and farmers’ well being, we should go back to the advice given by Jawaharlal Nehru in 1948, “Everything else can wait but not agriculture”.

IV
EXECUTIVE SUMMARY

CHAPTER II - INTEGRATED LIFE SAVING SUPPORT PROGRAMME FOR FARM FAMILIES FACING ACUTE DISTRESS

The reasons for farmers’ distress are many and varied. The low growth in agricultural per capita income is a major problem. The farmers also have to face climatic and market risks without satisfactory risk mitigation systems in position and extremely poor qualitative supply of services and inputs including credit. These constraints individually or in combination lead to poor returns and sometimes huge losses. When these take place repeatedly, the distress is acute. The cyclical nature of agriculture with occasional blessings has encouraged many small and marginal subsistence farmers to enter commercial agriculture from a position of extreme vulnerability. When their expectations are not met either due to natural or human factors, these farmers suffer a great deal. Then, there are events in the lives of the poor people like illness, accidents, large social expenditure, a major loss of asset or earning system/capacity, which drive them to the money lenders who charge high rate of interest and put harsh conditionalities to their loans. This further reduces their incomes and ultimately leads to loss of assets and finally land. With the weakening of community support as well as that of kin-networking, the farmers are driven to a state of helplessness and sorrow and in extreme cases to suicides.

2. The remedies are mainly the relief and rehabilitation measures in the event of disaster impacting a large area and their fine tuning, an effective community managed ‘Nutritional Security System’ on a life cycle basis, enhancing the productivity, profitability and stability of crop-livestock farming, creation of multiple livelihood opportunities in the farm, off-farm and non-farm sectors, improvement of the existing crop insurance system and introduction of an integrated insurance package covering accident/death/medical cover and loss to dwelling unit and other property due to fire/earthquake, etc.
3. The financial implications of taking up two immediate measures i.e., starting 10,000 community based grain banks initially in 38 out of 150 districts identified for the National `Food for Works’ Programme where the SC/ST population is more than 50% would work out to Rs.75 crore and for an integrated insurance covering accident risk, fire risk to the dwelling, natural death & medical cover for about two crore families would work out to Rs.310 crore for 2005-06.

4. The following other initiatives are suggested:

   (i) Create a National Level Steering Committee with representatives from the Govt.of India, IRDA, National Commission for Women, NABARD, IBA, NAIC, the four General Insurance Companies, SBI, the National Federation of State Cooperative Banks and one or two RRBs to oversee the development of rural insurance.

   (ii) NABARD and the Banks to broaden and deepen the Self Help Group linkages to Banks specially in the 150 identified districts and link those up with private sector/other institutions for backward & forward linkages for their products.

   (iii) Encourage establishment of private nursing homes/hospitals and Voluntary Health Services network in rural areas and block head quarters by providing tax holiday for five years and concessionality in bank credit. Such healthcare providers should agree to extend high quality but low or no cost medical facility to the poor.

   (iv) It would be useful to designate the small amount of financial help recommended for enabling the resource poor to take to insurance as life saving support and not as “subsidy, since such help is totally non-trade distorting. This will help to bring about a change in mindset with regard to saving the poor from acute distress.
PARIVAR BIMA POLICY

Based on a felt need and the IRDA decision to encourage micro insurance by allowing appointment of the Non Governmental Organisations (NGOs) and the Self Help Groups (SHGS) as agents for accepting insurance proposals upto Rs.10,000/-, an integrated family insurance policy named Parivar Bima Policy (PBP) providing floating cover for various risks other than crop and livestock has been devised. The proposed Policy could include mediclaim insurance providing reimbursement of hospitalization expenses for husband, wife and two dependent children upto Rs.10,000/- including transportation and meal charges not exceeding Rs.200/- and Rs.150/- respectively, life cover against natural death for Rs.5000/- for self (male or unmarried female taking the cover) or husband if the female is married, cover against accidental death or permanent total or permanent partial disability upto Rs.10,000/- and for insurance of dwelling unit for Rs.10,000/- to cover loss or damage to the house and contents (excluding jewellery) due to fire, lightning, riot, malicious damage, landslide, earthquake, etc. The policy thus covers the major risks which could seriously impact the life of the rural poor. The annual premium is likely to be around Rs.225/- p.a. (exact premium and the terms and conditions would, however, have to be firmed up in consultation with the Insurance Companies and IRDA). To facilitate larger coverage under the scheme, the NGO/SHG/Primary Agricultural Cooperatives (PACS) etc. could advance loan towards the premium cost to the insured and recover the same in installments. There is a potential of covering about 2 crore rural families under the PBP in the next two/three years.
EXECUTIVE SUMMARY

CHAPTER III – PRODUCTIVITY AND LIVELIHOOD
ENHANCEMENT IN RAINFED AREAS: TOWARDS A RAINBOW REVOLUTION

The greatest distress to farm and rural communities occurs in areas with low and uncertain rainfall, mainly in the arid and semi-arid regions of the country. The research and development work done in different parts of the country during the last 35 years has highlighted the need for the following concerted actions towards improving productivity and livelihoods in such areas:

(i) Capturing and conserving every drop of rainwater.
(ii) Enhancing the water infiltration and holding capacity and overall physical and chemical properties of the soils.
(iii) Cultivating crops which can perform optimally under conditions of water stress and scarcity.
(iv) Adopting a farming systems approach, with appropriate blends of crop-livestock integration.
(v) Improved post harvest technology and value addition to crop and animal products.

2. The principal constraints observed in reaping the full benefits from dryland farming research are the following:

(i) Lack of a watersheds approach, with all members of the watershed community working together to save and share water.
(ii) Lack of social synergy in the area of land and water use planning, with emphasis on collaborative efforts in both the production and post harvest phases of farming.
Dry lands soils are both thirsty and hungry. It is important that steps are taken to overcome these two constraints by judicious water harvesting and use, and by applying to the soil the needed micro- and macro-nutrients. The hidden hunger of the soil caused by micronutrient deficiencies needs to be addressed on a priority basis.

Major Recommendations

3. Establish a National Network of Advanced Soil Testing Laboratories capable of testing large volumes of soil samples for 16 macro and micronutrients – 1000 laboratories in all parts of the country, with 500 of them being located in dry farming areas, where there is scope for doubling average yields immediately through addressing the deficiencies of micro-nutrients in the soil, in addition to attending the needs for N, P, K.

4. Highest priority should be given to augmenting water availability by vigorously promoting rainwater harvesting, restoring water bodies and a million wells recharge programmes.

5. Convergence and synergy of all agricultural programmes around a watershed: We have recommended the formation of a National Federation of Farm Technology Missions which can assist the watershed community to access the provisions of appropriate technology missions like those relating to oilseeds, pulses, cotton, horticulture, dairy, etc. In addition, we propose the setting up at the national level a Commission for Sustainable Livelihood Security in Dry Farming Areas under the Chairmanship of an eminent farmer, who is an achiever in increasing productivity and income per every unit of water.

6. Lab to Land: Large-scale demonstrations should be organized on catalytic interventions both factor oriented, such as application of micro-nutrients for improving soil health and implements for improving soil physical properties (soil physics, chiseling
and enhancing rain water absorption) and system oriented, such as crop-livestock and crop-livestock-fish integrated systems. These would be undertaken in collaboration with CRIDA and ICRISAT.

7. Post harvest processing and value addition in collaboration with CFTRI and private sector should receive priority attention. A post harvest technology wing should be added to each Krishi Vigyan Kendra to bridge the gap between production and post harvest technologies and the KVKs may be redesignated as Krishi and Udyog Vigyan Kendras (KUVKs).

8. **Rainbow revolution** should be promoted in rainfed areas achieving substantial enhancement in the productivity of millets, pulses, oilseeds and livestock through large scale adoption of highly successful new technology packages, such as hybrid pigeonpea. Fifty thousand Farm Schools should be established in the fields of farmer-achievers.

9. Create pulses and oilseeds villages (eg. *Arhar* Villages, Sesame Villages) for specialized enhanced production (ensuring full availability of quality seeds and other specified inputs), efficient processing and remunerative producer-oriented marketing of the selected crops as well as the optimization of producing more crops and income per every drop of water by cultivating low water-requiring crops.

**Financial Provision in the Union Budget for 2005-06**

10. The following allocations are recommended:

(i) 1,000 advanced soil testing laboratories across the country, with 500 of them located in dry farming areas, each laboratory costing Rs. 50 lakhs - total allocation Rs. 500 crore.

(ii) 5,000 large-scale demonstrations on catalytic interventions in collaboration with CRIDA and ICRISAT, establishment of 1,500 seed banks and creation of 6,000 Small Holders’ Estates - Rs. 100 crore.
(iii) Establishing 50,000 Farm Schools in the fields of framer-achievers - Rs. 150 crore.

(iv) Post harvest processing and value addition in collaboration with CFTRI and private sector and strengthening of Krishi and Udyog Vigyan Kendras for post harvest management - Rs. 150 crore.

(v) Augmenting water availability by vigorously promoting water harvesting and restoring water bodies – Rs. 70 crore.

(vi) Million Wells Recharge Programme (to be promoted through interest rebate on loans)

(vii) Rainbow Revolution in rainfed areas achieving substantial enhancement in productivity of millets, pulses, oilseeds and livestock through large scale adoption of highly successful new technology packages, such as hybrid arhar - Rs. 50 crore.

(viii) Creation of pulses and oilseeds villages (Arhar Villages, Sesamum Villages) for specialized enhanced production, efficient processing and remunerative producer-oriented marketing of the selected crops - Rs. 30 crore

**Recommended total allocation: Rs. 1,050 crore**
EXECUTIVE SUMMARY

CHAPTER IV: A NEW DEAL FOR WOMEN IN AGRICULTURE

Under its terms of reference, NCF is “to recommend measures for the credit, knowledge, skill, technological and marketing empowerment of women, taking into consideration the increasing feminization of agriculture and the proposed conferment of right to land ownership”. Women in agriculture include women farmers, share croppers and farm labourers. Though their role and contribution to agriculture is immense, it is not adequately recognized and measured and hence is not integrated into development planning and resource allocations for Plans / Budgets. This results not only in women suffering from hard work, long working hours, drudgery, poor nutrition and inadequate economic returns, but also leads to sub-optimal productivity at the national level. Women’s lack of title to land limits access to credit. Technical know-how and gender specific technologies also do not reach them. Further, their traditional wisdom and experience relating to biodiversity conservation and enhancement, seed selection and storage, water harvesting, risk-minimising agricultural practices, and sustainable use of natural resources are not adequately recognized and compensated.

2. Pro-active approaches and affirmative action strategies are needed particularly at legal, policy, strategy, programme and resource allocation levels to provide all the categories of women a level playing field in relation to their contributions in the areas of conservation, cultivation, consumption and commerce. The following priority action plan is recommended in this context.

3. Priority Action Plan:

   (i) Legal land titles including allotment of surplus land and joint pattas as well as equal returns for equal work have to be ensured through time-bound and well monitored State action. Steps should be taken to provide women access to Kisan Credit Cards and other forms of institutional credit.
(ii) The proposed Employment Guarantee Act as well as the implementation rules relating to the Protection of Plant Varieties and Farmers’ Rights Act (2001) and the Biodiversity Act (2002) should be engendered.

(iii) The on-going Food for Work programmes should provide adequate, timely and gender-specific work for women, especially to women-headed families; the concept of “work” in the case of women should include the organization of a wide variety of support services for women, such as crèches and day care centres, preparation of noon meals, etc.

(iv) In the 150 districts identified for EGS, support services and nutrition supplement, including temporary crèches, should be provided to pregnant women and mothers. Also, nutrition support should be extended to adolescent girls and infants in the 0-2 age group in 20 selected districts to begin with.

(v) Women self-help groups have to be at the core of initiatives for income generation along with close interaction with partner agencies.

(vi) Programmes covering biodiversity, Farmers’ Rights, food security at household and community levels, training, access to technology, information and credit have to promoted. The proposed Rural Knowledge Centres should promote quality, food safety, trade and legal literacy movements among women.

(vii) Engendering the Curriculum of Agricultural and Veterinary Universities, based on the Kerala Agricultural University model, should be made obligatory.
(viii) **A Gram Panchayat Mahila Fund** should be established to enable SHGs and other women’s groups to undertake community activities that help to meet essential gender specific needs.

(ix) The overall focus would have to be on the landless and land poor sections of women working in dryland farming systems, and the marginalized groups who find their access to natural resources dwindling.

(x) An institutional mechanism for policy formulation and oversight and gender audit is essential. This could be achieved through the establishment of a **National Board for New Deal for Women in Agriculture** headed by the Union Minister for Food and Agriculture, with the Union Ministers for Women and Child Development, Rural Development and Panchayati Raj serving as Co-chairs. The Board should include in its Membership representatives of various stakeholders including the National Commission for Women, State Women’s Development Corporations, Women’s Organisations, NGOs, financial institutions, academia and media.

4. **Financial Provision in the Union Budget for 2005-06:**

The following allocations are recommended:

(i) **Gram Panchayat Mahila Fund @ Rs.2 lakhs each for 10,000 panchayats** – Rs. 200 Crore

(ii) **Day Care Cum Nutrition for 0-2 years children of poor rural women** – Rs. 500 Crore

(iii) **Support to women SHGs and other women’s groups for taking up common activities for women including women’s toilets, market yards, worksheds, etc., @ Rs.1 lakh for 2500 selected groups** – Rs. 25 Crore.

(iv) **Preparation of engendered curriculum in Farm Universities, Regional consultations on the issue of land title to women, meetings of the National**
Board for New Deal for Women in Agriculture and of an Expert Group for engendering the EGS and Food for Work Programme – Rs. 1 crore.
EXECUTIVE SUMMARY
CHAPTER V - STRENGTHENING AND EXPANDING THE HORTICULTURE REVOLUTION

The “horticultural revolution” during the past 10-15 years, led by Maharashtra and a few other States, has resulted in considerable expansion of horticultural production and consumption. However, the overall horticultural productivity has shown little change and the productivity of fruits and plantation crops has declined during the past decade. Moreover, little is known of the benefits reaching the small and marginal farmers and landless agricultural workers. The impact has also been skewed geographically as several States did not benefit from the opportunity and the investments made. The serious mismatch between production and consumption continues due to heavy post harvest losses, poor processing, low value addition and disorganized marketing. The ongoing Horticultural Technology Mission for North Eastern Region holds good promise but its four Mini Missions are disjointed and so far not much has happened in the highest priority area of post harvest management, processing and marketing.

Major Recommendations

2. In order to provide focused attention to the high priority areas in the proposed National Horticultural Mission aiming to uplift both the rural economy and national nutritional security, we would like to suggest the following:

(i) **A National Horticulture Council** may be established with the Union Minister of Agriculture as its Chairman and the Union Ministers of the other concerned Ministries as Members, which should ensure synergy and convergence among the sectoral missions (the Mini Missions) of the National Mission.

(ii) An agro-ecologically and socio-economically differentiated approach should be adopted to cater to the needs and potential of the different agro-ecological
settings and sectors of the society viz. small farmers, tribals, landless labour and women’s groups.

(iii) Based on the studies done so far, a pilot insurance project for horticultural crops should be launched under the existing National Agriculture Insurance Scheme.

(iv) In order to ensure convergence and synergy among the four Mini Missions, a National Mission Director, who must be an eminent horticulturist with outstanding achievements in horticultural research and development, should be appointed. He/she alongwith the coordinators of the different Mini Missions should identify the priority horticultural species and areas of activities through a participatory mode, particularly taking note of the needs and potential of the small holders. Highest priority should be given to prevention of post harvest losses, processing, value addition and marketing; the NDDB model and other successful models of production–processing–marketing integration should be replicated widely.

(v) Rejuvenation of old plantations and replanting senile and unproductive orchards, production and distribution of certified planting materials, implementation of SPS measures and other regulatory mechanisms and skill development should be undertaken on priority basis.

(vi) The long standing serious diseases of major fruits viz. malformation, alternate bearing and spongy tissue of mango, should receive highest attention of researchers and technology developers.

(vii) Small farmers’ SHGs should be helped to organize themselves as Small Farmers’ Horticulture Estates (SFHE) covering an area of 200 to 500 ha. each, to capture the economies of the scale. Landless labour should be supported in specialized activities, particularly with women self help groups
for beekeeping, vermicompost, production of bio agents, tissue culture and other planting materials. Young graduates should be engaged in precision horticulture, e-trading, establishment and management of agri-clinics, and soil and pesticide testing. Low cost green houses and fertigation should be actively promoted. The KVKs and ATMAs should also perform the role of Udyog Vigyan Kendras.

(viii) The successful experience of Maharashtra and of other places should be shared widely through organizing: (i) visits to “bright” spots, (ii) linking horticulture to national Food for Work and National Rural Employment Guarantee Schemes, (iii) revitalizing the NHB on the lines of NDDB and (iv) engendering all horticultural programmes.

Financial Provisions in the Union Budget

3. Rs. 21,699 crore is already proposed under the NHM for the next seven years. The resources may be reallocated according to the priorities suggested in this Report, especially the following areas:

(i) Organization of Small Farmers’ Horticulture Estates
(ii) Post harvest management, processing and marketing
(iii) Production and distribution of quality seeds and planting materials
(iv) Imparting quality literacy.
EXECUTIVE SUMMARY

CHAPTER VI - ENHANCING COTTON PRODUCTIVITY, QUALITY AND GLOBAL COMPETITIVENESS

Cotton, coupled with the cotton-based textile industry, is the largest employer and income provider in India, second only to agriculture as a whole. With the coming to an end of the multi-fiber agreement on the 1st January, 2005, our cotton producers, weavers, and the textile industry will encounter both new opportunities and threats. Therefore, synergistic interaction among all the stakeholders in the country is needed to enhance the efficiency of cotton production, processing and marketing.

Major Recommendations

2. India’s cotton production is besieged with low yields, poorer fibre quality, deteriorating soil health, heavy pest infestation and excessive use of pesticides and poor supply of quality seed and other inputs. The following public policy actions are recommended for alleviating these constraints towards enhancing cotton productivity and competitiveness:

   (i) Establishment of a National Cotton Council to serve as the apex level coordinating body comprising multiple stakeholders under the Chairmanship of the Union Minister for Agriculture, with the Union Minister for Textiles serving as Co-Chairman.

   (ii) Ensuring remunerative prices to the farmers and promoting farmer-centered marketing; since the landed price of cotton this year is somewhat lower than the price prevailing in the domestic market, the import duty may be raised from 10% at present to 30%, barring that on extra long fine cottons. Appropriate levels of export tariff may be provided for maintaining the farmers’ income and the overall cotton economy.

XIX
(iii) Appointment of a **Mission Director**, who must be an eminent cotton improvement and production expert, to integrate and coordinate the work of and to bring convergence and synergy among the four Mini Missions.

(iv) **Expanding the role of Cotton Corporation of India** in insulating the farmers from the wide price fluctuations and to advise them on the quality and varieties of cotton to be grown.

3. Priority should be accorded to the following research and technology transfer programmes.

   (i) Consistent with the bio-security requirements, promotion and development of Bt cotton and other bio-technologically designed varieties.
   (ii) Widespread adoption of new *arboreum* varieties and hybrids.
   (iii) Improvement of fiber quality to meet international standards.
   (iv) Correction of micronutrient deficiencies and carbon enrichment of soils.
   (v) Adoption of new water retention and management practices.
   (vi) Wide adoption and integration of IPM and IRM.
   (vii) Production and distribution of quality seed, biopesticides and bioagents.

4. Biomass utilization should be promoted for enhanced income and job security.

5. Establishment of **Small Farmers’ Cotton Estates**, each covering 500-1000 hectare, to increase efficiency and to provide small producers with the economies of scale, combining the advantages of production by masses with mass production technologies by fostering decentralized production supported by key centralized services at the production and post harvest phases. Each Estate can be supported by an Agri-clinic and Agri-business center operated by Farm Graduates. The Small Farmers’ Cotton Estate can each host a Rural Knowledge Centre based on modern Information and Communication Technology (ICT).
6. Credit, insurance, marketing may all be included in the Estate. The design of the Small Farmers’ Cotton Estates should be such that it represents a win-win situation for all participating farmers. Production, processing and marketing can be dealt with in an integrated manner.

Financial Provision

7. The following additional financial provisions are recommended for 2005-06:

(i) Establishment of 100 Small Farmers’ Cotton Estates, each covering 500-1000 hectare, - Rs. 175 crore
(ii) Research and technology transfer through integrated technology demonstrations - Rs. 50 crore
(iii) Promotion of biomass utilization - Rs.25 crore.

Recommended total allocation: Rs. 250 crore
EXECUTIVE SUMMARY

CHAPTER: VII - SUSTAINING AND EXPANDING FARM COMMODITIES TRADE: SANITARY AND PHYTOSANITARY DIMENSIONS

India’s preparedness in the field of Sanitary and Phytosanitary (SPS) measures is highly inadequate. As a result of this, several consignments of Indian farm exports were rejected in recent past. The situation is likely to get serious in the coming years since health safety standards as presented by Codex Alimentarius are getting increasingly stringent and the goal posts in developed countries have been shifting very fast. Thus, there is need for urgently launching a quality and food safety literacy movement in the villages and strengthening of SPS infrastructure.

2. We should also strengthen our quarantine facilities as several invasive weeds, pests and diseases have been introduced in the country along with grain, seed and planting material imports. About 50, important pests not yet in India, but found in the trading partner countries, could enter our country if not checked and destroyed at the border, or else these will destroy our agriculture. The Asian Flu disease of chicken in South East Asia is a case in point.

Major Recommendations

3. In view of the urgency of the steps needed both to safeguard our agricultural exports and to capture new markets, the following steps are suggested:

(i) establishing a Food Safety Council of India chaired by the Union Minister Agriculture with the Union Commerce Minister as Co-Chairman. There should be wide representation of members especially from major exporting States, both women and men covering all aspects of crops, livestock, fisheries and herbals.
(ii) augmenting and creating Survey, Surveillance and Quality Literacy Programme
(iii) strengthening SPS infrastructure and capacity
(iv) generating awareness abroad on steps taken in India to maintain high standards regarding food safety and biosecurity.

Financial Resources Required

4. To meet the above requirements and challenges of SPS Agreement, the country needs:

(i) comprehensive operation systems at all strategic points
(ii) credible diagnostic and accreditation system
(iii) science–based Pest Risk Assessment (PRA) and management
(iv) surveillance systems
(v) information, awareness and databases
(vi) audit and quality control system and enhanced quality and food safety standards.

To attain the above outputs and for spreading Codex Alimentarius standards, an additional sum of Rs 100 crore is required for the next two years, of which Rs. 60 crore is proposed during 2005-06.
EXECUTIVE SUMMARY

CHAPTER VIII: TOWARDS AN ERA OF KNOWLEDGE INTENSIVE AGRICULTURE MISSION 2007: EVERY VILLAGE A KNOWLEDGE CENTRE

Ecologically sound agriculture is knowledge intensive. Information empowerment of farm men and women on agriculture and allied activities, as also knowledge empowerment on a variety of issues ranging from health, education, on-farm and off-farm livelihoods, enterprise development, market linkages and quality literacy is the need of the hour. This can be effectively done through a network of Rural / Village Knowledge Centres harnessing ICT and other modern tools of communication.

These centres could operate from either the Panchayat building or village school or Study Centre of an open university and be designed on the underlying principles of social inclusion, gender equity and reaching out to remote areas and vulnerable populations. A National Alliance for MISSION 2007: Every Village a Knowledge Centre has been formed to mobilize the power of partnership among the public and private sector, academia, mass media and civil society organizations, to work together in making this vision a reality. The initiative calls for public policy support under the USO Fund and for a proactive Rural ICT policy including a community radio policy, and for public investment primarily in the areas of connectivity and setting up and operation of the Rural Knowledge Centres. There is also a felt need for Farmers’ Distress Call Centres in each State to provide timely and effective aid to farmers during periods of crises.

The four major components of Mission 2007 are Connectivity, Content, Capacity Building and Care & Management. India is in the fortunate position of being able to connect all the 600,000 villages speedily. BSNL and all the other agencies working on connectivity, including educational institutions like IIT, Chennai, should join together in fostering the rural connectivity movement. The Content has to be location specific and need based. A wide range of agencies will have to be involved for creation of relevant
content and brought under the umbrella of a National Digital Gateway for Rural Livelihood Security. A blend of non-formal training approaches, content creation in a virtual mode and its use at the Village Knowledge Centres is necessary for making a mass impact. A district level Content Consortium can be formed in each district. Again a District level Capacity Building Consortium can help to organise capacity building programmes using the pedagogic methodology of learning by doing. The care of the equipment and management of the knowledge centre can be undertaken by trained ICT-SHGs linked to Panchayats.

In this manner, an integrated self-sustaining and self-replicating system of Village Knowledge Centres can be built up. These Centres will be powerful vehicles for making the Right to Information (at the correct time and place) a reality.

It is proposed to establish 20,000 Rural Knowledge Centres covering 100,000 villages in the 150 less developed districts identified by the Planning Commission, on a priority basis in 2005. Investment support of Rs.500 crore for this is sought from the Ministry of Panchayati Raj and the USO Fund under the Ministry of Communications and Information Technology. The Ministry of Panchayati Raj is also requested to make an allocation for setting up RKCs in each Panchayat, provide for training of managers of these centres (Rural Virtual Academicians), extend incentives to rural service providers, and outsource revenue generating services to these centres (Rs.150 crore). The Farmers’ Distress Call Centres may be set up by the Ministry of Agriculture (Rs.100 crore). The creation of the National Digital Gateway for Rural Livelihood Security needs an allocation of Rs.100 crore. An Innovation Fund for rural connectivity and incentives for Rural Service Providers is called for under the USO Fund (Rs.500 crore). Banks and Financial institutions may extend low interest loans to ICT-SHGs that will manage the RKCs, to encourage ICT-based entrepreneurship (Rs.100 crore). The Ministry of Information and Broadcasting is requested to frame a community radio policy for the country and provide licenses to 4000 community radio stations in the coming year. The total financial support that will be needed from USO and the Ministries of Agriculture and Panchayati Raj during 2005-06 will be of the order of Rs.1450 crore. Such an investment will enable our villages to leapfrog in promoting knowledge intensive
agriculture and agri-business and in providing opportunities for a healthy and productive life to everyone in the village.
EXECUTIVE SUMMARY

CHAPTER IX - FOOD AND NUTRITION SECURITY

Under its terms of reference, NCF has been called upon “to work out a comprehensive medium-term strategy for food and nutrition security in order to move towards the goal of universal food security over time”. The serious hunger problems in our country relate to under-nutrition caused by inadequate purchasing power, and micro-nutrient malnutrition or hidden hunger caused by both poverty and lack of nutritional literacy. Inspite of striking progress in improving agricultural production, India is the home of the largest number of undernourished children, women and men. This unenviable reputation is unnecessary and inexcusable.

2. Nutrition Security involves economic, physical, social and environmental access to balanced diet and safe drinking water. The country has the capacity to achieve freedom from chronic hunger speedily through the introduction of an interactive and decentralized Nutrition Security programme under the supervision of Panchayats.

3. Ultimately, the country should introduce a Food Guarantee Scheme, combining the features of Employment Guarantee and Food for Work. A National Committee for a Hunger Free India may be set up under the Chairmanship of the Prime Minister, with the Union Minister for Food and Agriculture and Co-Chair, for preparing a road map for launching such a National Food Guarantee Programme. The National Committee should include in its membership Chief Ministers of States characterized by the high incidence of hunger hot spots.

There is also need to bring about a paradigm shift in the delivery of nutrition support programmes from a department-centred to a human life-cycle centred approach.

5. The following allocations are recommended during 2005-06 for moving towards the goal of achieving relative freedom from hunger by 15th August, 2007, which marks the 60th anniversary of our independence:

XXVII
i) Supplementary nutrition for adolescent girls, pregnant women and 0-2 age group children – 250,000 tons of food grains

ii) Nutrition support to HIV/AIDS/Tuberculosis affected rural women and men – 100,000 tons of food grains.

iii) Elimination of hidden hunger caused by the deficiency of iron, iodine, zinc and Vitamin A – Rs.200 crore

iv) Establishment of Community Food and Fodder Banks – Rs.75 crore for 10,000 Community Food Banks as recommended in Chapter II and Rs.25 crore for Fodder Banks.
EXECUTIVE SUMMARY

CHAPTER X – LIVESTOCK AND LIVELIHOODS

The ownership of livestock is much more egalitarian than that of land. Livestock are particularly important in arid and semi-arid areas for strengthening household livelihood and food security. The Diary and Poultry sectors, which are already playing a key role in enhancing income and nutrition, need additional attention from the point of view of the following needs.

2. **Diary:** Under and mal-nutrition of livestock cause reduced milk yield. There is need for intensifying production and distribution of fodder and feed, since most of the dairy animals are stall-fed. Fodder and Feed Banks operated by SHGs would help landless labour families to take to animal husbandry.

3. There is urgent need for a **Livestock Food Corporation** organized jointly by NDDB, SFAC and NABARD to promote and assist SHGs to undertake fodder and feed production. It is suggested that a sum of Rs.100 crore may be provided in the budget of 2005-06 to support SHGs undertaking the production of fodder and feed. Also fodder production (both perennial and annual fodder) should receive priority in the EGS and Food for Work programme.

4. **Poultry:** Resource poor farmers, particularly belonging to SC/ST rural communities can be assisted to form **Poultry Estates** based on the provision of key centralized services to support decentralized production. The help of the Egg Coordination Council and organized poultry companies in the private sector may be taken to integrate poultry farming in the **Engendered Sustainable Livelihood Security Movement**.

5. The sanitary and phytosanitary measures should be strengthened to avoid the introduction of invasive alien pests and pathogens.
EXECUTIVE SUMMARY

CHAPTER XI - BEYOND TSUNAMI: SAVING LIVES AND LIVELIHOODS

The Tsunami disaster has provided a unique opportunity for launching through public-private sector partnership an integrated psychological, ecological, agronomic and livelihood rehabilitation programme. Rehabilitation efforts in the recent tsunami affected areas have to be adopted for operation across three time dimensions: Immediate (Jan-Mar 2005), Medium term (2005-07) and Long Term (2005-10), in order to alleviate the distress of the affected fisher and farm families.

2. The immediate is in terms of i) psychological rehabilitation by way of counseling to recover from the trauma and ii) livelihood rehabilitation. It is recommended that A Special Food for Livelihood Revival and Eco-protection programme be initiated in the affected areas to create assets for the tsunami ravaged families. It is recommended that 300,000 tonnes of food grains be allotted immediately for this programme.

3. The medium and long-term strategies should cover all families along the coast and fall into three broad categories –

   a) Ecological rehabilitation through coastal bio-shields, participatory management and enhancement of coastal mangroves forests and other wetlands, promotion of community nurseries of species chosen for the bio-shield and agro-forestry programmes, regeneration of fisheries, raising of artificial coral reefs, management of marine biosphere reserves, special attention to housing through a human security driven design of coastal habitations and construction of permanent sea walls in places where there is heavy sea erosion. There should be a Code of Conduct for construction beyond 500 metres.

XXX
b) Agronomic rehabilitation through reclamation of salinised soils. This has to be done on a priority basis the help of Agricultural Universities, ICAR and CSIR. A consortium of R&D institutions set up jointly by the Department of Ocean Development, Department of Science and Technology, and Indian Meteorological Department, Government of India should map human and agricultural vulnerability to potential changes in sea level. Scientific land and water use planning will have to be done to prevent salinisation of ground water.

c) Livelihood Rehabilitation through a sustainable strategy based on the principles of social inclusion and gender equity. Aquatrain Policy should focus on conservation and sustainable use of living aquatic resources, harmony between artesenal and mechanized fishing and equitable sharing of benefits, promotion of Sea Water Farming and establishment of Coastal Biovillages. Aquaculture Estates in the Biovillages can help confer the power of scale to fisher families and lateral learning should be promoted through a coastal grid of farm schools and demonstration centers.

4. A network of Rural Knowledge Centres should be established all along the coast as soon as possible and capacity built for disaster preparedness and management
SERVING FARMERS AND SAVING FARMING

COMPOSITE FINANCIAL SUMMARY

Chapter II: Integrated Life saving support Programme for
Farm families facing acute distress

1. Community Grain Banks numbering 10,000 in the hunger
hot-spots in the 150 Districts identified for National Food
for Work Programme. Rs. 75 crore

1. Parivar Bima Policy for healthcare accidents and loss of
property. Rs. 260 crore

3. Rural Insurance Development Fund - Rs. 50 crore

Sub-total: Rs. 385 Crore

Chapter III: Productivity and Livelihood Enhancement in Rainfed
Areas: Towards a Rainbow Revolution

1. Million Wells Recharge Programme Interest rebate on
loans

2. Restoring Water Bodies and Promoting Water Harvesting Rs. 70 crore

3. Soil Health Enhancement through a National Network
of 1000 soil testing laboratories Rs. 500 crore

4. 50,000 Farm Schools in the fields of farmer-achievers Rs. 150 crore

5. Krishi Vigyan Kendras for post-harvest
processing and value addition Rs. 100 crore

6. Large-scale demonstrations of dryland farming
technologies, overcoming micronutrient deficiencies
in the soil, organisation of farmers’ groups,
establishment of seed banks and popularisation
of hybrid *arhar*

Sub-total: Rs. 1050 Crore

XXXII
Chapter IV: A New Deal for Women in Agriculture

1. Supplementary nutrition for 0-2 years age group children in 20 selected districts Rs. 500 crore

2. Gram Panchayat Mahila Fund @ Rs. 2 lakhs for 10,000 selected Panchayats Rs. 200 crore

3. Support to women Self-Help Groups for taking up common activities for women including Ladies’ toilets, market yards, worksheds etc. @ Rs. 1 lakh for 2500 selected groups Rs. 25 crore

4. Promotion of engendered curriculum in Agricultural universities, Regional Consultations on land titles, Meetings of National Boards and Expert Group etc. Rs. 1 crore

Sub-total: Rs. 726 Crore

Chapter V: Strengthening and Expanding the Horticulture Revolution

1. About Rs. 15,000 Crore is already proposed under the NHB. Provision for the measures suggested in the Report will have to be made in the National Horticulture Mission.

Chapter VI: Enhancing Cotton Productivity, Quality and Global Competitiveness

1. Integrated Technology. Demonstrations including value addition to cotton biomass. Rs. 75 crore

2. Establishment of 100 Small Farmers’ Cotton Estates, each covering 1000 hectare to increase efficiency and provide small producers with the economies of scale, credit, insurance, marketing. (in addition to Budget of the Cotton Technology Mission) Rs. 175 crore

Sub-total: Rs. 250 Crore

Chapter VII: Strengthening Sanitary and Phytosanitary Measures

1. Imparting quality and trade literacy, meeting codex alimentarius standards and preventing the introduction of invasive alien species. Rs. 60 Crore

XXXIII
Chapter VIII: Every Village a Knowledge Centre

1. Mobilizing Information Communication Technologies (ICT) for the knowledge empowerment of rural families in areas relating to weather, water, health, education, nutrition, agriculture, markets and government entitlements through Village Knowledge Centres. Rs 750 crore

2. Establishment of a National Digital Highway for Rural Livelihood Security. Rs 100 crore

3. Establishment of Farmers’ Distress Call Centres. Rs 100 crore

4. Establishment of 20,000 Rural Knowledge Centres. Rs 500 crore

Sub-total: Rs. 1450.00 Crore

Chapter IX: Hunger Free India

1. Supplementary nutrition for adolescent girls, pregnant women and 0-2 age group children 2.5 lakh tonnes of food grains

2. Nutrition support to HIV/AIDS/Tuberculosis affected rural women and men. 1.0 lakh tonnes of food grains

3. Elimination of hidden hunger caused by the deficiency of iron, iodine, zinc and Vitamin A. Rs. 200 crore

4. Establishment of Community Food and Fodder Banks. Rs. 25 crore

Sub-total: Rs. 225 Crore + 3.5 lakh tonnes of food grains

Chapter X: Livestock and Livelihoods

1. Organisation of Livestock Food Corporation of India jointly by NDB, SFAC and NABARD for Fodder; and establishment of Small Farmers Poultry Estates. Rs. 100 Crore

Sub Total: Rs 100 Crore
Chapter XI: Beyond Tsunami: Saving Lives and Livelihoods

1. Food for Livelihood Revival and Eco-protection Programme
   3.0 lakh tonnes of food grains
   Grand Total: Rs. 3496.00 Crore
   + 6.5 lakh tonnes of food grains.

Abbreviations:

7. CRIDA - Centre for Research in Dryland Agriculture
8. ICRISAT - International Centre for Research in Semi-Arid Tropics
9. CFTRI - Central Food Technology Research Institute
10. SHG - Self Help Group
11. NGO - Non-Government Organisation
12. NHB - National Horticulture Board
13. NDDB - National Dairy Development Board
14. SPS - Sanitary and Phytosanitary
15. EGS - Employment Guarantee Scheme
16. USO - Universal Service Obligation
17. ICT - Information Communication Technology
COMPOSITE ADMINISTRATIVE INITIATIVES

Chapter I: Wake-up Call

Chapter II: Integrated Life Saving support programme for farm families facing acute distress

1. Create a National Level Steering Committee with representatives from the Govt. of India, IRDA, NCW, NABARD, IBA, NAIC, the four General Insurance Companies, SBI, the National Federation of State Cooperative Banks and one or two RRBs to oversee the development of rural insurance.

2. NABARD and the Banks to broaden and deepen the Self Help Group linkages to Banks specially in the 150 identified districts and link those up with private sector/other institutions for backward & forward linkages for their products.

3. Encourage establishment of private nursing homes/hospitals and Voluntary Health Services network in rural areas and block head quarters by providing tax holiday for five years and concessionality in bank credit.

Chapter III: Productivity and Livelihood Enhancement in Rainfed Areas: Towards a Rainbow Revolution

1. Establishment of a National Network of Advanced Soil Testing Laboratories- 1000 laboratories in all, with 500 in dry farming areas.

2. Million Wells Recharge Programme during 2005-06 by providing a rebate on interest.

3. Establishment of 50,000 Farm Schools in the farms of farmer-achievers.

4. Formation of Federation of Farm Technology Mission for assisting the water-shed community to access the appropriate technology missions.

5. Setting up a Commission for Sustainable Livelihood Security in Dry Farming Areas under the Chairmanship of an eminent farmer.
6. Demonstration on catalytic interventions in collaboration with CRIDA and ICRISAT.

7. Post harvest processing and value addition in collaboration with CFTRI and private sector. Adding a Post Harvest Wing to each Krishi Vigyan Kendra and redesignating them as Krishi and Udyog Vigyan Kendra.

8. Rainbow Revolution in rainfed areas achieving substantial enhancement in productivity of millets, pulses, oilseeds and livestock through large scale demonstrations of highly successful new technology packages, such as hybrid pigeonpea.

9. Creation of pulses and oilseeds villages (eg. Arhar Villages, Sesame Villages) for enhanced production, efficient processing and remunerative producer-oriented marketing of selected crops as well as the optimization of production of crops and income for every drop of water by cultivating low water-requiring crops.

Chapter IV: A New Deal for Women in Agriculture

1. Legal land titles including allotment of surplus land and joint pattas as well as equal rights for equal work have to be ensured through time-bound and well-monitored State Action.

2. Women self-help groups have to be at the core of initiatives along with close interaction with partner agencies.

3. Programmes covering bio-diversity, food security at household and community levels, training, access to technology, information and credit have to be ensured.

4. Support services and nutrition supplement for expectant and mothers especially through temporary crèches at work sites, particularly in 20 selected districts out of the 150 districts identified for EGS. To begin with, nutrition for children in the 0-2 age group in view of their vulnerability.

5. Margin money for Women’s SHGs for undertaking common productive activities for farming women.

6. Engendering of curriculum in Agriculture Universities based on Kerala Agricultural University model.

7. A Gram Panchayat Mahila Fund for women to enable SHGs of women to undertake community activities that help to meet essential gender specific needs.

8. Overall focus would have to be on the landless and land poor sections of women working in dryland farming systems and the marginalized groups who find their access to natural resources dwindling.
9. Establishment of a National Board for Women in Agriculture headed by Union Minister for Agriculture and co-chaired by Union Minister for Women & Child Development and Union Minister for Panchayati Raj, and consisting of various stakeholders including NGOs, financial institutions, academia, media etc. for policy oversight and gender audit.

Chapter V: Strengthening and Expanding the Horticulture Revolution

1. A National Horticulture Council may be established with the Union Minister of Agriculture as its Chairman.

2. A pilot insurance project for horticultural crops may be launched.

3. A National Mission Director may be appointed to identify the priority horticultural species and areas of activities.

4. Small farmers SHGs may be helped to organize themselves into Small Farmers’ Horticulture Estates covering an area of 200 to 500 hectares to capture the economies of scale.

5. The successful experience of Maharashtra and of other places should be shared widely through organizing (i) visits to “bright” spots, (ii) linking horticulture to National Food for Work and National Rural Employment Guarantee Schemes, (iii) revitalizing the NHB on the lines of NDDB and (iv) engendering all horticulture programmes.

Chapter VI: Enhancing Cotton Productivity, Quality and Global Competitiveness

1. Establishment of a National Cotton Council to serve as the apex level coordinating body comprising multiple stakeholders under the Chairmanship of the Union Minister for Agriculture, with the Union Minister for Textiles serving as Co-chairperson.

2. Import duty on cotton may raised from 10% to 30%, barring the extra long fine cotton. Appropriate levels of export tariff may be provided for maintaining the farmers’ income and the overall cotton economy.

3. A Mission Director may be appointed to integrate and coordinate the work of the four Mini Missions.

4. The role of Cotton Corporation of India may be expanded for insulating the farmers from wide price fluctuations and to advise farmers on the quality and variety of cotton to be grown.
5. Small Farmers Cotton Estates may be established to increase efficiency and to provide small producers with the economies of scale. Credit, insurance and marketing may all be included in the Estates and supported by an Agri-clinic and Agri-business centres.

Chapter VII: Sustaining and Expanding Farm Commodities Trade: Sanitary and Phytosanitary Dimensions

1. Establishment of Food Safety Council of India chaired by the Union Minister of Agriculture with the Union Commerce Minister as Co-Chairperson and representation from all stakeholders.

2. Survey, Surveillance and Quality Literacy Programme.

4. Generating awareness abroad on steps taken in India to maintain high standards regarding food safety and biosecurity.

Chapter VIII: Towards an Era of Knowledge Intensive Agriculture Mission 2007: Every Village a Knowledge Centre

1. Establishment of 20,000 Rural Knowledge Centres (RKC) covering 1 lakh villages in 150 districts identified by the Planning Commission for EGS.

2. Establishment of RKCs in each Panchayat, providing for training of managers of these centres, extending incentives to rural service providers, and outsourcing revenue generating services to these centres.

3. Establishment of Farmers’ Distress Call Centres.

5. Establishment of an Innovation Fund for Rural Connectivity and incentives for rural service providers under the USO Fund.

6. Access to low interest loans to ICT-SHG from banks and financial institutions.

7. Developing a new policy to encourage the spread of Community Radio(FM) and license to 4000 community Radio Stations.

XXXIX
Chapter IX: Hunger Free India

1. Setting up of a National Committee for Hunger Free India under the chairmanship of the Prime Minister, with the Union Minister for Food and Agriculture as Co-chair for preparing a Road Map for launching a National Food Guarantee Programme, combining the features of Employment Guarantee and Food for Work.

2. Establishment of a Food Safety Council of India with the Union Minister for Food and Agriculture as Chairman and the Union Minister for Health and Commerce as Co-chairs.

3. Supplementary nutrition for adolescent girls, pregnant women and 0–2 age group children.

5. Programme for elimination of hidden hunger caused by the deficiency of iron, iodine, zinc and Vitamin A.

Chapter X:-Livestock and Livelihoods

1. Organisation of Livestock Food Corporation of India jointly by NDDB, SFAC and NABARD for stimulating and supporting Fodder; and Feed Producing SHGs.

2. Formation of Poultry Estates by resource poor farmers for achieving centralized services to support decentralized production with the help of the Egg Coordination Council.

3. Strengthening of the sanitary and phytosanitary measures to avoid introduction of invasive alien pests and pathogens.

Chapter XI: Beyond Tsunami: Saving Lives and Livelihoods

1. Setting up of a Committee under the chairmanship of Union Home Minister, to monitor progress in the implementation of the integrated rehabilitation strategy suggested by NCF for Tsunami affected regions.
2. Launching of Special Food for Livelihood Revival and Eco-protection Programme in Tsunami affected areas.

3. Fostering a Coastal Bio-shield programme for minimizing the fury of cyclonic storms and tidal waves.

4. Fostering a Coastal Bio-village Movement for providing multiple livelihood opportunities.

5. Organising a network of Rural Knowledge Centres in Coastal villages.

6. Aquarian Reforms for promoting sustainable fisheries

CHAPTER I

WAKE-UP CALL

“Forget the past, Remember every day dawns for us from the moment we wake up. Let us all, every one, wake up now”

Mahatma Gandhi, January 1948

This report is designed to serve both as a wake-up call to the nation on the deteriorating farm conditions, as well as on the opportunities available to enhance our global agricultural competitiveness and to overcome to a great extent the scourges of endemic and hidden hunger now affecting nearly 25% of our population by 15 August, 2007, which marks the 60th anniversary of “our tryst with destiny”, to quote Jawaharlal Nehru’s historic words. Our agriculture is at the crossroad economically, ecologically, technologically, socially and nutritionally. A “business as usual approach” in the farm sector now will lead to an unprecedented human calamity, the beginnings of which we are now witnessing in the form of suicides by farmers in several parts of the country, including the Punjab which is the heartland of intensive agriculture.

2. In order to recommend policies, programmes and measures for accelerated, diversified agricultural development, that would alleviate rural poverty and raise the standard of living of the farmers’ community in the new millennium, a National Commission on Farmers was set up vide Resolution dated 10th February 2004 of the Ministry of Agriculture, Government of India, under the Chairmanship of Shri Som Pal and consisting of two Full-time Members and three Part-time Members in addition to a Member Secretary.

Following the installation of the United Progressive Alliance (UPA) Government in the Centre, it was deemed necessary to revise the Terms of Reference and Composition of the Commission in order to reflect the priorities and concerns outlined in the Common Minimum Programme. Accordingly, the Commission was reconstituted under the Chairmanship of Prof. M.S.Swaminathan. The terms of reference and the composition of NCF are in Annexure 1.
Prof M S Swaminathan joined as Chairman, NCF on 11 August 2004. Since then, the Commission has held consultations with State Governments, financial and insurance institutions, representatives of farm and tribal women and men, and civil society organizations, academia and media representatives working on problems relating to farming and farmers. In addition to several meetings in New Delhi, consultations were held at Cochin, Chennai, Hyderabad, Jeypore (Orissa), Ahmedabad, Shillong, Dehra Dun and Mumbai. Ensuring the income, work and livelihood security of farming families through enhancing the productivity, profitability and sustainability of the major farming systems, strengthening the food and nutrition security of the nation, imparting value addition to the time and labour of assetless agricultural labour families through technological and skill empowerment, ensuring gender justice and equity in all agricultural development programmes, and involving Panchayati Raj institutions in fostering environmentally sustainable agricultural progress have been the basic principles in the approach of NCF to fostering agrarian prosperity and rural livelihood and ecological security.

3. **Challenges**

Farm families in India constitute over two thirds of the population. Since farmers are also consumers, the sharp distinction often made in industrialized countries between the interests of farmers and consumers, is not valid in the Indian context. Detailed analyses of the causes of food insecurity in rural and urban areas have revealed that the major cause of under- and malnutrition among children, women and men is the lack of adequate purchasing power to permit access to balanced diets and clean drinking water. Therefore, NCF feels that a 3-pronged strategy needs to be introduced to ensure the economic well-being and nutrition security of rural families. First, families possessing assets like land, livestock or fish ponds will have to be assisted to enhance the productivity of their resource endowments in an environmentally and economically sustainable manner. The smaller the holding, the greater is the need for marketable surplus. Hence, the highest emphasis has to be placed on increasing output per units of land, water, nutrients and labour based on technologies which are ecologically and economically sound. For this, we need more research on the development of eco-technologies based on blending traditional ecological prudence with frontier technologies like information and biotechnology and space and renewable energy technologies.
Second, nearly a third of the rural population and a large proportion of women earn their livelihood through wage employment. They have no assets like land or livestock or fish ponds and are also often illiterate. The challenge in the case of landless agricultural labour is enhancing the economic value of their time and labour by bringing about a paradigm shift from unskilled to skilled work. A massive effort in the area of knowledge and skill empowerment of the women and men constituting the landless labour work force is essential if economic value is to be added to their time and labour. They will have to be enabled to take to skilled non-farm employment through market-driven micro-enterprises supported by micro-credit. Self-help Groups (SHGs) of assetless women and men will have to be made sustainable through backward linkages to credit and technology and forward linkages with markets. Common property resources will have to be developed and managed in a manner that they can provide essential support systems in areas such as fodder and feed for stall-fed animal husbandry as well as fuel wood. At the same time, the unfinished segments of land reform including the distribution of ceiling surplus land to assetless families should be attended to with speed and commitment. The interests of unregistered cultivators, tenants and tribal cultivators will have to be safeguarded.

The third group are rural artisans working in the secondary and tertiary sectors of the economy. Their skills will have to be mobilized to enhance the competitiveness of agriculture through value-addition to primary products and diversification of livelihood opportunities. The strategy for the technological upgradation of rural professions should be based on the principle of social inclusion.

Thus, the three pronged strategy consists of improving the productivity of land, water, livestock and labour in the case of asset owning farm families, converting unskilled agricultural labour into skilled entrepreneurs engaged in organizing market-driven non-farm enterprises, and enhancing the skills of families involved in the secondary and tertiary sectors of the rural economy, so that they are able to assist in improving agricultural efficiency and competitiveness and in ending the prevailing mismatch between production and post-harvest technologies.

4. **Threats:**

First, the ecological foundations essential for sustained advances in productivity, such as soil, water, biodiversity and forests are under severe anthropogenic pressures. The human and
farm animal population supporting capacity of the ecosystem has been exceeded in many parts of the country. The quantity and quality of ground water, which is now the dominant source of irrigation water, is fast deteriorating. Although India has over 20% of the world’s farm animal population, good grazing lands are practically non-existent. Compounding current problems, the possibility of adverse changes in precipitation, temperature and sea level due to global warming and climate change is no longer just a theoretical conjecture.

Second, in the area of farm economics, resource flow to the agriculture sector is declining and indebtedness of small and marginal farm families is rising. Input costs are increasing, while factor productivity is declining. Contrary to the general impression of agrarian prosperity in the Punjab, the total debt in the farm sector has been estimated to have increased from Rs.5,700 crore in 1996-97 to Rs. 11,133 crore in 2002-03. The average farm debt in the Punjab now exceeds a lakh of rupees (Rs. 1,01,210), out of which more than 40% is provided by non-institutional sources at an interest rate of nearly 24% per annum. The cost-risk-return structure of farming is becoming adverse to over 80 million farming families operating small holdings, since the resource poor families cultivating 1 to 2 ha or less are unable to benefit from the power of scale at both the production and post-harvest phases of farming.

Third, a technology fatigue has further aggravated farmers’ problems, since smaller the farm the greater is the need for sustained marketable surplus, in order to have cash income. Linkages between the laboratory and the field have weakened and extension services have often little to extend by way of location, time and farming system specific information and advice. Good quality seeds at affordable prices are in short supply and spurious pesticides and biofertilizers are being sold in the absence of effective quality control systems. Input supply is in a disarray particularly in dry farming areas. Micronutrient deficiencies in the soil as well as problems relating to soil physics are crying for attention. Farmers have no way of getting proactive advice on land use based on meteorological and marketing factors. Though it is now over ten years since the WTO regime started operating in agriculture, serious attempts are yet to be made to launch in rural areas movements for quality literacy (sanitary and phytosanitary measures and codex alimentarius standards of food safety), trade literacy (likely demand-supply and price situation) legal literacy (IPR, Farmers’ Rights) and genetic literacy (genetically
modified crops). No wonder the prevailing gap between potential and actual yields even with technologies currently on the shelf is very wide (Table 1).

5. In the area of technology, there is also need to bridge the growing digital and genetic divides. Post-harvest technology is poor and there is little value addition particularly in the case of fruits, vegetables and spices including a wide range of tubers and medicinal and aromatic plants. Sustainable intensification, ecologically, economically and nutritionally desirable diversification and value addition to the entire biomass are important for raising small and marginal farm families above subsistence level. All this will call for initiating an era of knowledge intensive agriculture. Modern information communication technologies (ICT) afford an opportunity for launching a knowledge revolution in rural India. The torch bearers of this revolution should be rural women and men. **Participatory research and knowledge management involving farm women and men should be the principal pathways of research, education and extension. Farmers should be regarded as partners and innovators in bringing about agricultural transformation and not as beneficiaries of government programmes. Such a change in mindset among government functionaries is essential for progress.**

Technologies should help in promoting labour diversification and not displacement. Women farmers and labour particularly need to be assisted with implements and equipment which will help to reduce drudgery and the number of hours of work, while adding economic value to each hour of work. Women suffer from a multiple burden on their time due to home making and keeping, child rearing and income earning responsibilities. They need appropriate support services like crèches and child care centres and adequate nutrition. The feminisation of agriculture, due to male outmigration, needs specific attention with reference to gender sensitive
farm and credit policies. **All research and development programmes in agriculture must be engendered.**

Revitalisation of small farmer-friendly technologies should be based on sound principles of economics and participatory research and knowledge management. If for example, rice-wheat rotation is not desirable in the Punjab from the standpoint of ecological sustainability, the alternative farming systems proposed should be capable of yielding similar income. **Agronomic data should not only indicate yield per hectare of land, but also the likely return from every rupee invested and every liter of water used by the farmer.** Lateral learning among farm women and men should be fostered, since farmer to farmer learning is based on the principle – “one ounce of practice is worth tons of theory”. India is also the home of some of the best farm families in the world. In the midst of many hunger and agro-ecological “hot spots”, there are also numerous farming “bright spots”. In order to multiply the benefits from the experience and skills of outstanding farm men and women, **Farm Schools** should be established in their fields.

6. **Priorities:**

Based on Consultations with State Governments as well as discussions with farm and tribal women and men and media representatives, a few areas were identified for priority public policy support and financial allocation in the Union and State budgets for 2005-06. A business plan approach was adopted while developing the immediate, “save farmers and farming action plan”, since we are aware that our proposals should not merely be desirable, but **should be actionable and affordable.** We would like to stress that agriculture being a State subject, State governments also have the responsibility of providing adequate support particularly to meet the needs of location-specific agricultural problems, as well as the health, education, drinking water and other social and production infrastructure essential for farm and agricultural labour families to have an opportunity for a healthy and productive life. Public policies which are likely to result in **ecocides** (i.e. ecological suicides) should be avoided. Pandemics like HIV/AIDS and Tuberculosis need to be checked, if our agriculture is not to experience the kind of human disease-induced setback currently occurring in several countries in Africa.
Based on such considerations, the following areas have been identified for adequate support in the Union and State budgets of 2005-06:

A. **Life-saving support for farm families experiencing acute distress due to a combination of meteorological, marketing, technological, social and credit and input management factors:** The causes for the distress are diverse and there is no simple or single remedy. Our immediate suggestions relate to risk management through a basket of insurance options, and streamlining of delivery systems relating to credit and other entitlements. At the same time, a beginning can be made in the 150 districts identified for the National Food for Work programme to form consortia of public and private sector agencies for assisting resource poor farm women and men to strengthen their livelihood security through additional on-farm and off-farm income. The private sector can particularly play a vital role by helping to provide assured and remunerative marketing avenues for farm produce and for the products produced by SHGs. Outsourcing of manufacturing tasks from urban to rural areas should be fostered.

B. **Productivity and Livelihood Enhancement in rainfed areas.** The major pathway has to be productivity enhancement and the cultivation of high-value but low-water requiring crops. A catalytic intervention which will help to increase productivity immediately is attention to soil healthcare. The provision of micronutrients like sulfur, zinc and boron can help to increase yield by over 50% in dryland farming areas. Facilities for identifying and remedying micro-nutrient deficiencies in soils are urgently needed. **Soil Health Clinics** can be operated by SHGs comprising rural women and men who can issue each farm family with a **Soil Health Card.** Also, livestock and livelihoods are closely inter-related in dry farming, semi-arid and arid-areas. Hence, the establishment of fodder and feed banks should receive urgent attention. The gap between available scientific know-how and field level do how is very large in dryland farming areas. Bridging the productivity gap in an economically viable manner is the best safety net against farmers’ distress in such areas. For accelerating progress in finding lasting solutions to the economic woes of farmers and agricultural labour, it would be useful to form District-level consortia of private and public sector institutions willing to help in improving small farm income and off-farm employment opportunities.
C. **Small Farmers’ Horticulture Estates.** The cultivation of fruits, vegetables, flowers, spices, medicinal and aromatic plants is now happening in a big way in several parts of the country. Being perishable commodities, horticultural crops need effective infrastructure support in the areas of production, processing, storage, transportation and marketing. In villages adjoining large consumption centres (both for home and export markets), small farmers can be helped to organise **Small Farmers’ Horticulture Estates** in the form of SHGs covering an area of 200 to 500 hectares. In such Estates, specialized activities like seed production, tissue culture propagation, production of compost, vermiculture, biofertilizers, biopesticides and e-commerce can be promoted through technological and credit empowerment. Such Estates will confer on farmers cultivating one to two hectares the power of scale both at the production and post-harvest phases of the horticultural enterprise. Low cost green houses coupled with fertigation techniques can be promoted, in addition to high-tech horticulture which can be undertaken by farm and home science graduates. The production of good quality, disease-free planting material is important in all clonally propagated species. Also, seeds and planting materials of varieties suitable for processing will have to be provided to farmers in areas where production and processing are linked. Such symbiotic linkages between producers and processors will facilitate sourcing of good quality raw material for the processing industry.

D. **Enhancing the productivity of cotton and the global competitiveness of the cotton textile industry:**

The textile sector is a major employment and income providing sector of the national economy. With the coming to an end of the multi-fibre arrangement on 1\textsuperscript{st} January, 2005, our cotton producers, weavers and the textile industry will encounter both new opportunities and threats. Without enhanced efficiency, it will be impossible to take advantage of the emerging market opportunities. Technological upgrading of all the components of the cotton production – processing – marketing cycle, will be needed to prevent this vital sector of our economy, particularly with reference to both employment and export earning potential, from setbacks. A productivity, quality and value addition revolution is urgently needed in cotton production and processing. To provide overall
coordination and policy support it will be advisable to establish a Multi-stakeholder National Cotton Council, with the Union Ministers for Agriculture & Food and for Textiles as Chair and Co-Chair of the proposed National Cotton Council.

E. Women farmers and farm labour:

There is increasing feminisation of agriculture in families with small and marginal holdings, due to the out-migration of men. The problem is particularly severe in hill areas like Uttaranchal, Jharkhand and the N.E. States. Yet, out of nearly 44 million Kisan Credit Cards so far issued in the country, less than 10 percent seem to have been issued to women (precise data are not available). The proposed conferment of land rights to women will help to redress this distressing situation. Meanwhile, joint pattas will have to be issued to make women eligible for institutional credit. Also, women working the whole day in the field require support services like crèches and day care centres. A unique opportunity now exists for engendering the ongoing National Food for Work programme by enlarging the concept of work in the case of women by including such initial activities like running crèches and child care centres, preparing school noon meals, undertaking immunization of children, providing family planning services, etc. The curriculum of Agricultural, Veterinary, Forestry and Fisheries Colleges should be engendered without further delay.

F. Every Village a Knowledge Centre:

India’s strength in ICT provides uncommon opportunities for taking digital and knowledge connectivity to every village in the country by August 15, 2007. Reaching the unreached and voicing the voiceless will be possible through an integrated ICT strategy involving the internet, community radio, cable TV and vernacular press. The fibre optic network of Bharat Sanchar Nigam Ltd (BSNL), comprising 30,000 exchanges, covers all the 6,000 blocks of the country. If each exchange is extended to 20 nearby villages, all the 600,000 villages can be covered at minimal expenditure. It is unfortunate that out of 16 tetra bits of international connectivity available now, only 0.35 tetra bits have been lit. Less than 0.20 tetra bits are being used. We should aim to leapfrog in spreading the power of the digital age to rural India.
The Rural Knowledge Centres should be located in public spaces like Panchayat Centres or Village Schools, so that there is social inclusion in access. The National Alliance for Mission 2007: Every Village a Knowledge Centre and the Jamsetji Tata National Virtual Academy for Rural Prosperity are effective instruments for launching knowledge based agriculture and rural non-farm enterprises. Panchayat Raj institutions will have to play a leading role. NABARD, SBI and other financial institutions can support Rural ICT SHGs, who can maintain and operate the Knowledge Centres. Connectivity, content, capacity building, care and management of the Knowledge Centre will all need integrated attention to make the movement socially meaningful and economically sustainable.

G. Building a Sustainable Nutrition Security System:

Nutrition security is best defined as “physical, economic, social and environment access to balanced diet and clean drinking water for all and for ever”. The Central and State Governments have initiated from time to time a large number of nutrition safety net programmes. An accelerated advance in achieving the goal of nutrition security at the level of every child, woman and man will be possible through the following interactive steps:

- Deliver all nutrition support programmes on a whole life cycle basis and fill up gaps in ongoing programmes, such as the nutritional needs of adolescent girls, pregnant women and 0-2 infants.

- Ensure access to clean drinking water, environmental hygiene, primary healthcare and primary education.

- Take special steps to overcome hidden hunger caused by micronutrient deficiencies like iron, iodine, zinc and Vitamin A.

- Promote the cultivation and consumption of fruits and vegetables as well as of dairy products.

- Facilitate the setting up of local level community Food Banks, comprising locally grown grains like millets and legumes, thereby enlarging the
composition of the food basket. Also, promote the setting up of Fodder and Feed Banks, since livestock and livelihoods are intimately related in most parts of the country, particularly in semi-arid and arid areas.

- Generate awareness about the human and farm animal population supporting capacity of the ecosystem, in order to generate interest in population stabilization.

- Launch a massive movement in rural areas for additional employment and income generations. The on-going Self-help Group (SHG) revolution should be made sustainable through backward linkages with technology and credit and forward linkages with markets.

- Provide nutrition support to rural women and men suffering from HIV/AIDS and Tuberculosis.

Such a local level Nutrition Security Compact is best designed and managed by SHGs operating under the oversight of the Gram Panchayat and Gram Sabha. We should also plan to launch a Food Guarantee Scheme by integrating the principles of Employment Guarantee and Food for Work programmes.

H. Employment generation in Agriculture:

In the ultimate analysis, a sustainable end to hunger can be achieved only by providing opportunities for every woman and man to earn their daily bread. A detailed strategy for creating additional skilled jobs through horticulture, cotton, energy plantations, animal husbandry, biofuels and biomass utilization is being developed. India is rich in livestock resources. Nearly 20% of the farm animal population are in India. Crop-livestock integrated production systems can help to enhance both household nutrition security and cash income. Over-riding priority should go to fighting the famine of jobs / sustainable livelihood opportunities through the creation of economically rewarding and intellectually stimulating work opportunities in villages. This is the only way to attract and retain educated youth in villages.
7. **Uncommon Opportunities:**

This first report is designed to assist Central and State Governments to arrest the decline of farm income and farmers’ distress. It provides implementable and affordable suggestions for triggering an agriculture-led economic and livelihood revolution. No further time should be lost in taking advantage of the opportunities for saving farmers and farming through the opportunities highlighted in this report in the form of business plans.

There are numerous institutional structures already available to Government, like SFAC, NHB, NDDB, Agri-clinics, Agri-business Centres, Food Parks, Agro-export Zones, several Commodity Centred Technology Missions, Watershed and Wasteland Development Programmes etc. Instead of starting many new schemes, what is needed is the revitalization and restructuring of existing schemes and institutional structures and the retooling and retaining of existing staff. Also, we are suggesting ways of minimizing transaction costs and improving delivery efficiency through convergence and synergy among the numerous on-going vertically structured programmes.

The initiation of a National Rural Employment Guarantee scheme together with an expanded Food for Work Programme provides a unique opportunity for launching a multi-pronged attack on poverty and rural unemployment. Engendered work under this programme can become a catalyst of a long term sustainable livelihood security movement in the different ecological, hydrological and farmers’ distress hot spot regions of the country.

NCF feels that all the above programmes will have to be implemented in a decentralized manner with authority and accountability being linked at the field level. The 11th Schedule of the Constitution Seventy-Third Amendment Act 1992 on The Panchayats lists agriculture, including agricultural extension as the very first responsibility of Panchayats (Article 243 G). Other items including Animal husbandry, dairying and poultry, fisheries, minor irrigation, water management, watershed development, land improvement, implementation of land reforms and land consolidation and soil conservation are also the responsibilities of Panchayats. Therefore they should
be actively involved in the detailed planning and implementation of the priority action plan proposed in this Report.

8. **Malady – remedy Analysis**

The crisis in our agriculture has arisen because of lack of appropriate public policies as well as adequate public investment in rural infrastructure. Therefore, the cures for the prevailing maladies can be found only in public policies and investment. Spending by Central and State Governments in strengthening the ecological, technological and social foundations for sustained advances in farm productivity has been going down. Most of the money spent by Central and State Governments goes to the salaries of government officers and employees. Consequently, rural infrastructure including power, irrigation, market yards, rural godowns and communication, as well as vital sectors like health and education remain grossly under-funded.

Declining credit-deposit ratios in rural areas, volatility of prices, weak research and extension and neglect of women farmers and farm labour have all added to the woes of the farming community. Indebtedness of farmers is rising not only because of farming related expenditure, but also because of the need for money for healthcare. The public healthcare system in villages is in a state of collapse. Pandemics like HIV/AIDS and Tuberculosis are spreading in villages. Because of protein-energy under-nutrition as well as micro-nutrient deficiencies, a purely drug based approach to the control of diseases is not adequate. A nutrition support programme is equally important. Thus, there is need for a holistic approach in addressing the technological, financial, health, educational and marketing problems faced by farm women and men.

The crucial role of women farmers and labour in agriculture is yet to receive recognition. Women play a key role in all the four major components of farming, namely, conservation, cultivation, consumption and commerce. Until the commitment to provide land rights to women is fulfilled, it is important to ensure that joint pattas making women eligible for Kisan Credit Cards and institutional credit, are issued without further delay. 2005 marks the tenth anniversary of the Beijing Conference on Women and Development which drew attention to the growing feminisation of agriculture and of
poverty. Therefore it will be appropriate to introduce in the 2005-06 budget a **New Deal for Women in Agriculture**. The various components of such a New Deal are described in this Report. Credit, insurance, technology development and dissemination, healthcare, education, input supply, output marketing and rural employment and food for work programmes should all be engendered.

Another area which needs urgent attention is the economy of scale in farm holdings. The average size of farm holding has declined from 2.69 h.a. in 1960-61 to 1.41 h.a. in 1995-96. The process of decline in the size of an operational holding is continuing. There are now about 115.6 million farms. The use of purchased inputs by farmers has multiplied 283 times during 1950-51 to 2000-01. To meet input costs, the rural poor borrow 84% of their credit needs from non-formal sources. The quantities of marketable surplus have multiplied to the tune of 10 times of cereals, 4.6 times of oilseeds, 5.3 times of milk, 15.4 times of poultry products and 7.4 times of fish during the last 50 years. Yet, post-harvest infrastructure is weak. Even now farmers in several parts of the country dry the freshly harvested paddy on paved roads, where there is often heavy vehicular traffic. Drying yards are a luxury in a majority of villages.

Value addition in the case of horticulture products is less than 10%. The gross marketing margin in farm commodities is estimated at Rs.1009 billion, out of which nearly 70% is accounted by marketing cost. About 77% of marketing costs are estimated to be avoidable losses during handling, storage and transport. Quality, labeling, brands, taxes, subsidies, sanitary and phytosanitary (SPS) issues, price volatility, removal of quantitative restrictions on imports and the absence of a level playing field in international trade due to the very high support (nearly 1 billion dollars per day for 10 million farming families) extended to farmers in OECD countries, are all becoming significant factors in agricultural marketing.

9. **Enhancing Agricultural Competitiveness: Basket of Choices**

Raising the agricultural competitiveness of farmers with small holdings is a major challenge. Methods of conferring the power of scale to small farm families both at the production and post-harvest phases of farming is an urgent necessity. A basket of
choices should be available to farm women and men cultivating 1 or 2 h.a. or below to enhance their income earning capacity. Productivity improvement to increase the marketable surplus available to small farm families, assured and remunerative marketing opportunities, and creating opportunities for landless agricultural labour families for skilled non-farm employment should be the bottom line of public policy. The basket of choices for enhancing productivity, profitability and sustainability could include the following:-

a) Formation of Self-help groups of farm families to undertake group operations in areas like water harvesting and management, pest management and post-harvest technology. Some examples are: Small Farmers’ Horticulture, Cotton and Poultry Estates.

b) **Promotion of contract farming** to ensure assured marketing outlets on the basis of a well defined Code of Conduct; the **Code of Conduct for Contract farming** should include provision of support to small producers in the areas of technology and input supply and fair price for the produce.

c) Revitalising and restructuring various government schemes like Agri-clinics, Agri-business centres, Rural Godowns, Small Farmers Agri-Business Consortium (SFAC), National Horticulture Board, etc. so as to make them farmer centric.

d) Promoting the active involvement of Panchayati Raj institutions and local bodies to foster Water-shed/Command Area Communities and making the Water-shed or the irrigation command area the point of convergence and integration of all relevant Technology Missions like those relating to oilseeds, pulses, maize, cotton, horticulture, milk, etc. Convergence and Synergy among the numerous Technology Missions now in progress will improve their utility and impact and also help to reduce overall transaction costs. All the Missions could be integrated under an umbrella set-up which could be termed “**National Federation**
of Farm Technology Missions”. The ongoing Missions operating on parallel lines appear to have very little accountability, since in spite of their existence, imports of pulses and oilseeds are going up. Pulses and oilseeds are important nutrition and income providing crops in rainfed areas and farmers in dry farming areas will continue to suffer in poverty and deprivation unless the proposed National Federation of Farm Technology Missions extends to them the needed help at the right time and place. Such a National Federation is best Chaired by a practicing farm woman or man, who has a proven record of unleashing the power of creativity in small farm management. Its major aim should be to enhance farm productivity and agrarian and rural prosperity.

10. **Resources**

   The underlying principles governing our recommendations are affordability and implementability. Catalytic actions are needed to achieve more from the available resources. The resource use and mobilization strategy of NCF has the following four components:

   a) Maximise the benefits from the resources allotted to agriculture by the Central and State Governments by bringing about convergence and synergy among the numerous on-going programmes with the active involvement of Panchayats and local bodies. An example is the proposal to use the watershed or command area of an irrigation project as the hub of all appropriate Technology Missions and create for this purpose a National Federation of Farm Technology Missions chaired by an outstanding farmer.

   b) Make additional allocations to fill critical gaps in essential rural and agricultural infrastructure and services, including education, irrigation and post-harvest technology.

   c) Enable small farm families to maximize the benefits of their land, livestock and other assets by bridging the prevailing gap between scientific know-how and field
level do-how through mutually reinforcing packages of technology services and public policies.

d) Help rural families without assets like land, livestock or fish pond to take to skilled non-farm employment through market driven micro-enterprises supported by micro-credit.

e) Promote the effective implementation of all land reform measures, including the distribution of ceiling surplus land to antyodaya families and the security of tenure in the case of tenant and tribal farmers.

11. **Critical role of education and healthcare**

   The important steps recommended by NCF, such as value addition to primary products, turning unskilled into skilled labour and using digital technology in villages, require for effective implementation an educated population, with minimum level of Class X education. Unless all children in our villages, especially girls, dalits and rural poor get educated, the goals of social equity and agrarian and rural prosperity cannot be achieved. Until formal literacy becomes universal, the techniracy movement (i.e. learning the latest technical skills through work experience) should be spread. For this Krishi Vigyan Kendras should be developed into Krishi Aur Udyog Vigyan Kendras, with equal emphasis on production and post-harvest technologies. Farm Schools can also be established in the fields of innovative farmers.

   Along with education, healthcare facilities for the rural poor need to be strengthened. There is need to increase substantially public investment both in elementary education and healthcare in rural India.

12. **Addressing Five Basic Needs**

   Asset reform, technology, water, credit and producer-oriented market are among the five basic needs of farm women and men. Hence, these critical factors need to be taken into account in plans designed to reverse the prevailing farmers’ distress. We have accorded priority attention to them in the action plans described in this Report. Since
water is vital for agriculture, action in ensuring water security for agriculture as well as for domestic and industrial purpose needs overriding priority. A few suggestions relating to the building of a sustainable water security system are therefore given based on the initiatives outlined by the Union Finance Minister, Shri P. Chidambaram, in the budget for 2004-05.

13. **Policy for Water for Agriculture**

   The lack of availability of water has become the most critical limiting input for Indian agriculture. Farmers from across the country say that water shortage, during drought and even during non-drought years, is destroying their ability to grow food. What is often not appreciated is that groundwater irrigates a larger area than surface water; over 60 percent of the cropped area in the country. Another 20 percent of the agricultural area is irrigated using groundwater in conjunction with tanks and canals. Groundwater levels are declining sharply. This is partly because technology is allowing for deeper and deeper penetration and extraction, with little regulation over use or misuse. The Central Groundwater Board estimates that 65% of the districts in the country are over-exploited from the point of view of ground water. The electricity subsidy worsens the situation, with estimations that farmers end up using almost double the water for each unit of crop when they have access to cheap or free power as compared to pumpsets using paid diesel. But worse, electricity supply to farmers is always uncertain and unreliable, which affects their capacities to take decisions. It is imperative, therefore, that any policy for agricultural reform, must take into account the need to evolve programmes for recharge and management of the groundwater reserves of the country.

   It is also clear that farmers will remain dependent on rainfall water for agriculture. Rainfed agriculture, however, risky and vulnerable, continues to play an important role in India, contributing 60 percent of the cropped area and 45 percent of the total agricultural output. There is a need for renewed attention to programmes, which effectively address the challenge of improving productivity and reliability of rainfed agriculture.
In this context, the programme announced by the Finance Minister Shri P. Chidambaram in his budget of 2004-05 to “launch a massive scheme to repair, renovate and restore all the water bodies that are linked to agriculture” is of paramount importance. We should put in place an effective and sustained programme for implementation of this programme so that we can provide water security and hence livelihood security to our farmers.

It is also worrying that drought is no longer a question of a failure or variation in the current rainfall, but one that concerns the increased vulnerabilities of the farm sector to cope and withstand shocks. It is important to note that drought, for the rural sector, is not only about the lack of drinking water or declined agriculture productivity, it is also about non-availability of fodder for animals. The shortages of fodder results in the loss of livestock, which in turn makes them weaker and more disabled to deal with the vagaries of the next season. Drought in this way does not remain a temporary phenomenon, but one that is permanently crippling. It is therefore, essential that not only does the country have an effective system for monsoon management and drought monitoring but also places renewed emphasis on grassland development so that food reserves of the country’s animals can be built along with the food banks of its people.

It is equally clear that water use is increasing in all sectors. Therefore, the use of water in agriculture will face greater and greater competition from others – in industry and urban areas – and this will inevitably lead to conflict. It is therefore important to begin to build policies for conserving water in all sectors, including agriculture. The use of water in agriculture is consumptive – in other words, the used water is consumed and ‘virtually’ transferred via a product – to us in our food. This is different from the use of water as a process, where water is mostly discharged after use and rejoins the water cycle. For instance, cities discharge 80 percent of the water consumed as sewage back to the hydrological system.

Policies will have to be built to optimize water use in both these broad sectors. In the case of agriculture we will have to invest in improving the yield per hectare and per unit of water consumed. A recent study shows that of the 660 billion cubic metres of
total consumptive use of water by crops, roughly 55 percent is accounted for by irrigated crops. While rice accounts for a little over 20 percent of all water consumed by all crops, wheat alone uses 30 percent of the irrigated water. Interestingly, while yields per unit of irrigated area are higher than in unirrigated areas, the yield per unit of consumptive use of water is not always higher – in fact, they are normally 10 to 30 percent lower. It is important for us to invest in research, which will promote water-efficient crops and do all we can to value each drop of water.

14. **Immediate Tasks.**

a) **Million wells recharge programme.**

Research from across the world as well as India suggests that groundwater is actually more productive (producing more crops per hectare) than surface water. This is because farmers who use groundwater can get as much water as they need, when and where they want. It is not surprising therefore, while canal irrigation was the main driver of irrigated agriculture in the 1970s, by the 1990s, groundwater had become the major force. Studies also suggest that small and marginal farms, which make up 29 percent of the total agricultural area, account for 38 percent of the net area irrigated by wells and 35 percent of the tubewells fitted with electric pump sets.

But the problem is that even as the use of groundwater has increased little has been done to recharge the aquifers so that as far as possible we can ensure that abstraction is limited only to what we can annually recharge. Today, much of the recharge is natural and incidental. This recharge depends on various factors like rainfall, soil characteristics and geomorphology. The Central Groundwater Board, which has calculated the rainfall infiltration factors for different hydrogeological situations in the country, estimates that the highest infiltration is between 20-25 percent (in sandy areas). There is a need to rebuild reserves through artificial recharge using rainfall and monsoon flows in rivers.

As yet, there is no government programme, which specifically targets the individual wells of farmers. It is estimated in various studies that there are roughly 19-20 million well owners in the country. This programme needs to be targeted towards each
well owner, encouraging them, with small financial assistance, to undertake a programme to recharge their well, by channelising the rainwater to the well. The cost of the individual well recharge is between Rs.1000-5000 as this depends on the cost of the filter that is needed to ensure that mud and soil do not enter the well. As the quantum required is very small and will lead to high transaction costs, we would suggest that the million well recharge programme is linked to a rebate in the rate of interest provided under the enhanced agricultural credit programme. In this way the programme will provide farmers an incentive to invest in well recharge, which in turn will make agricultural productivity more reliable and less risky.

b) **Rebuilding water bodies.**

The Finance Minister has already announced this programme. But being linked to an annual budget, there are constraints on the programme’s sustainability. It is important to understand that water harvesting is not about an instant (annual) miracle. It will take time and investment to rebuild our rural capital. We have to think of it like a bank account, which we have overdrawn upon. Similarly, our groundwater aquifers are in deep trouble. We need to replenish these speedily. It is clear that all villages, which have practiced water conservation between 7-10 years at a stretch are able to build capacity to withstand even prolonged drought. But the challenge is to build this programme with farm families, as they alone can invest in their water security.

**We would suggest a massive programme for water bodies with the objective to secure water and food security in the country.**

The programme may be organised as follows:

a. It must draw upon the current fragmented programmes – Drought Prone Areas Programme (DPAP), Desert Development Programme (DDP), National Watershed Development Programme for Rainfed Areas (NWDPRA), Integrated Watershed Development Projects and Programme (IWDP), the National Afforestation Programme (NAP) and the National Watershed Development Fund – for a common objective purpose to build water and livelihood security. There is
no apparent shortage of funds in this area. The task is to work towards an effective programme, which is driven by a common objective. For instance, the National Afforestation Programme alone has been allocated Rs 1,115 crore for the 10th plan. The work of this programme is to regenerate the forests, which in turn will rebuild the watersheds of agriculture.

b. The problem is that there is no enabling mechanism to effectively coordinate the delivery of the programme. The only mechanism is through the common approach guidelines evolved between the Ministries of Agriculture and Rural Development. This matter has been deliberated upon for many years, without much headway. We would therefore suggest that the best coordinating mechanism for these programmes is through the greater involvement of the Panchayati Raj department so that village communities play a direct and enabling role in the delivery of these schemes.

c. In addition, the programme must make use of the funds available in existing employment programmes – such as food for work, or the proposed employment guarantee programme as the main aim of labour in villages is to build natural assets.

d. Over and above this we would suggest enhanced allocation specifically for water bodies in the next budget, as an endowment fund. The 2004-05 budget provided for two specific programmes (restoring water bodies and water harvesting) with a financial allocation of Rs 200 crore. This allocation must be increased and provided as an endowment so that funds for this activity are available over a period of time, which will make it sustainable.

15. **National S&T Alliance for Rural Livelihood Security.**

At a consultation organized jointly by NCF and the Union Planning Commission at Delhi on 23rd December 2004, it was decided to form a National Alliance of S and T institutions in the public and private sectors to provide technical backstopping to the National Rural Employment Guarantee and National Food for Work programmes, so that the work undertaken leads to an engendered livelihood security system. The National
S&T Alliance for Rural Livelihood Security will bring together ICAR, CSIR, ICMR, ICSSR, Departments of Atomic Energy, Science and Technology, Biotechnology and Ocean Development, UGC, Ministry of Non-Conventional Energy Sources and other Central Government institutions, Agriculture, Rural and Women’s Universities, as well as private sector and civil society R&D institutions and Banks and financial institutions for the purpose of initiating in the 150 districts identified by the Planning Commission for special attention, an engendered sustainable livelihood security programme through knowledge, skill, information and market empowerment. The National S&T Alliance will be a virtual organization and will promote a multi-institutional and multi-disciplinary team effort to foster job-led economic growth in rural India. The areas of concern will include, besides the promotion of economically viable SHGs, health, education and nutrition. The S&T Alliance will aim to bring about confluence and synergy among the efforts of private, public and academic sector institutions to undertake a massive human resource development and capacity building programme, to begin with in the 150 districts chosen for the National Food for Work Programme. Sustainable SHG programmes based on poor-friendly technologies will be developed. The National S&T Alliance will be serviced by the National Academy of Agricultural Sciences.

The National S&T Alliance will promote the formation of similar alliances at the State level. The State level S&T consortium will be serviced by the appropriate State Agricultural University. At the district level, this programme will be linked to the DRDA. The District level S&T consortium will give priority to the following activities:

- Assisting local farm and landless labour families to access their entitlements
- Capacity building – building a cadre of Master Trainers
- Mentoring
- Establishing market linkages

The formation of National and State Level S&T Alliances for fostering economically sustainable and gender sensitive livelihood systems in villages will be an important step in mobilizing the power of partnership in ushering in an era of job led economic growth.
in rural India, based on a pro-poor, pro-women and pro-nature orientation to technology development and dissemination. Technology can then become an ally in the movement for gender and social equity.

16. **Soil Health Management.**

An important reason for the low return per unit of water is the lack of synergy between a genetic strain, irrigation water and soil nutrition. Hidden hunger in the soil resulting from micronutrient deficiencies results in hidden hunger in farm animals and human beings. We should strengthen our capacity to advise farmers on soil healthcare.

There is need for additional facilities for reliable soil test analysis for 13 macro and micronutrients, since this is critical for improving crop productivity. This requires sophisticated, finely-tuned equipment (atomic absorption spectrophotometer, UV spectrophotometer, etc.) that are currently unavailable in most soil testing laboratories. Implementation of the technology will require a quantum jump in the number of soil test laboratories and soil test analyses conducted throughout the country. Therefore it is advisable to establish new laboratories to supplement the existing network. Since the laboratory equipment requires frequent recalibration to maintain reliability, a national monitoring agency is also required to obtain and compare test results on standard samples on a monthly basis.

Initially it cannot be expected that farmers will fully appreciate the value of a complete soil test. Therefore, it is proposed that the Government conduct an intensive programme of free tests for the first one or two years, until the efficacy of the approach is demonstrated. Thereafter, fees can be charged to recover the cost of the tests and the cost of establishing additional laboratories. If a commercial fee structure is fixed of Rs 200 to 250 per test, then farm graduates will be attracted to supplement the government effort by establishing Agri-clinics which can undertake such tasks as soil health monitoring and management and pest proofing on an area basis. Agri-clinics can also be established in Farm Schools. A Project Design Team could be set up to work out the details on the lines indicated below.
1. Objective: To establish a national network of sophisticated soil testing laboratories capable of testing large volumes of soil samples on a full spectrum of 13 macro and micro nutrients.

2. Anticipated Benefits: To provide farmers with essential tools for doubling or tripling crop yields and farm incomes.

3. Actions Required by Government:
   - Conduct an inventory of all existing soil test labs to ascertain the type, age, condition and test volume capabilities.
   - For labs that report having the required equipment, conduct calibration tests to ensure that the equipment is working properly.
   - All labs that do possess the required equipment should be upgraded or supplemented by new labs.
   - Establish a national monitoring system to recalibrate all lab equipment on a monthly basis or as often as necessary to maintain test accuracy.

4) Programme Cost & Funding:
   - The objective should be to provide a complete soil test analysis at the commencement of each cropping season. Since accurate analysis requires limiting the sample size to three or four acres per sample, this will require approximately 25,000 to 50,000 tests per district per month. In the first phase there should be a minimum of one lab per district, each with the capacity to conduct a minimum of 10,000 complete soil analyses per month.
   - The cost of a new lab capable of processing 400 samples per day will be approximately Rs 30 lakhs for equipment.
   - Subsidies for comprehensive soil testing programme -- The materials cost for each complete soil test approximately Rs 150. The total cost of materials, labour, interest, and depreciation will come to about Rs 200 per test.

This is an investment which will yield a rich dividend.
17. **Technological upgrading of Farm Practices: Development of Computerised Farm Advisory System (CFAS)**

Soil test results will be of little value unless expert advice is available to the farmers to interpret the significance of nutrient levels and recommend appropriate steps to enhance soil nutrition. The required inputs will vary significantly from crop to crop. The most appropriate selection of inputs will also vary with fluctuations in input prices. **In order to service millions of farmers with timely and reliable interpretation, it is proposed that expert systems be developed for all major crops specifying the optimum levels of each nutrient required to compensate for soil deficiencies and produce maximum yields and net income for the farmer.**

a) Objectives:

- Create computerized expert systems for all major crops to provide recommendations based on soil tests and the steps needed for the farmer to achieve optimal yields and income.

- The expert system should cover at least 20 major crops and be customized to different agro-climatic zones.

b) Anticipated Benefits:

- Each farmer who submits soil for a soil test can receive an automated report specifying the crops most suitable for cultivation according to the soil profile and providing detailed instructions on how to enhance the soil to ensure proper plant nutrition for optimal yields and profitability.

- Quality of information can be the best in the world.

- Speed of service will be very high.

- Cost of delivering information will be very low.

c) Actions Required by Government:

- Recommending optimal cropping pattern options based on soil analysis, cost of inputs & prevailing market prices, including cost-benefit for each crop
Recommending optimal package of cultivation practices for specific crops based on field conditions & soil test results

- Generating detailed crop production instructions for the specific crop and field conditions.

d) Programme Cost & Funding:

- Major cost may be for acquisition of expert knowledge both from within the country and outside

- Cost for development of expert systems for interpretation of soil test results customized to different regions and types of soil is roughly estimated at Rs 10 to 25 lakhs per crop.

- This programme can be linked to the “Every Village a Knowledge Centre” movement.

18. **Farm Schools**

There are at present training facilities for farmers in Krishi Vigyan Kendras (KCKs) and farmers’ training centres of various kinds (Krishi Gyan Kendra, etc.) in different States. It is becoming clear that farmer to farmer learning is the most credible and effective. The numerous agricultural “bright spots” we see around the country are associated with the initiative of hard working and innovative farm men and women. Krishi Pandits, Karshaka Shris (an award in Kerala) and other outstanding farmers should be involved in participatory research and knowledge management systems in a more structured manner. For this purpose, we suggest that **Farm Schools** may be established in the fields of outstanding men and women farmers. Such Farm Schools will be based on the principles of learning by doing as well as “seeing and harvesting is believing”. The Farm Schools will help to impart a sense of grassroot realism to the capacity building programmes.
The Farm Schools can receive training and technical support on a continuing basis from a network of State level training centres, from the soil testing labs, the farm equipment hiring service and the expert computer system. The characteristics of the Farm Schools should be as follows:

a) Objectives:

- To establish a cost-effective system of on-farm training to farmers in every village of the country.

- To double agricultural productivity and farm incomes by dissemination of science-based agricultural technologies for plant nutrition, pest management and water conservation.

b) Anticipated Benefits:

- Cost-effective system for training 25 million farmers a year in advanced methods of agricultural production.

- Improved dissemination of technology by demonstrating advanced agricultural production practices on farmers’ lands in the village.

c) Strategy:

- Promote the establishment of 50,000 village-based farm schools throughout the country, on the farms of innovative farm men and women supported by Agricultural and Rural Universities / ICAR institutes.

- All agro-industries, KVKs, agricultural colleges and research institutes to assist in setting up village based farm schools on farmers’ fields.

- Agricultural graduates and lead farmers to be certified as instructors and offered incentives for establishing private farm schools to train local farmers.
- Establish central and satellite farm production training institutes in each state to train and certify farm school instructors.

- Multimedia training materials to be developed for training farm school instructors and for farmer training.

- Computerised expert systems to be developed for crop selection, soil nutrition, identification and treatment of pests.

- Farm schools to be linked to Rural Knowledge Centres to provide access to multimedia training materials, computerized expert systems, web-based technical and marketing information.

d) Programme Cost & Funding:

- Based on a model project developed for Tamil Nadu, a State-wide system for farm school training, extension, soil labs, and agro-services, including multimedia training materials and computerised experts for farm management capable of generating and supporting 50000 farm schools may require an initial investment of approximately Rs 150 crore.

The on-going Agri-clinic scheme could be restructured to include the establishment of Farm Schools. Also, special Farm Schools can be established to spread the expertise of outstanding farm families who have achieved great proficiency in water harvesting and management, wasteland development, horticulture, agro-forestry, organic farming, poultry and animal husbandry and coastal and inland aquaculture. It is suggested that Rs.150 crore may be allotted for initiating a well organized programme for accelerated agricultural progress with the help of achievers in farming.

19. We must begin the process of imparting dynamism and optimism in the farm sector, as was done in the nineteen sixties. Accelerated agricultural progress based on the enhancement of productivity, sustainability and profitability through farming systems diversification, sustainable intensification, quality upgradation and value addition, is vital
not only for food security and poverty eradication, but also for national sovereignty. Jawaharlal Nehru’s often quoted remark made in 1948 “Everything else can wait, but not agriculture” is even more relevant today. Let us therefore wake up both to the fast spreading agrarian crisis and to the opportunities available for converting the crisis into an era of restructuring and strengthening the support systems for the over 110 million farming families in the country (they constitute 25% of the global farming population).
Annexure I

The Terms of Reference of the National Commission on Farmers are as under:\footnote{Resolution dated 3rd November, 2004, Ministry of Agriculture (Department of Agriculture & Cooperation)}

- Work out a comprehensive medium-term strategy for food and nutrition security in the country in order to move towards the goal of universal food security over time.

- Propose methods of enhancing the productivity, profitability, stability and sustainability of the major farming systems of the country based on an agro-ecological and agro-climatic approach and the harnessing of frontier technologies.

- Bring about synergy between technology and public policy and recommend measures for enhancing income and employment potential in rural areas through diversification, application of appropriate technology including IT for information on market, weather, credit facilities and e-commerce, training and market reforms.

- Suggest measures to attract and retain educated youth in farming and recommend for this purpose; methods of technological upgrading of crop husbandry, horticulture, animal husbandry, fisheries (inland and marine), agro-forestry and agro-processing and associated marketing infrastructure.

- Suggest comprehensive policy reforms designed to enhance investment in agri-research, substantially increase flow of rural credit to farmers including small and marginal, triggering agricultural growth and economic progress, which can lead to opportunities for a healthy and productive life to rural families.

- Formulate special programmes for dryland farming for farmers in the arid and semi-arid regions, as well as for farmers in hilly and coastal areas in order to link the livelihood security of the farming communities living in such areas with the ecological security of such regions. Review in this context, all ongoing Technology Missions like those relating to pulses, oilseeds, maize, cotton, watershed etc. and recommend methods of promoting horizontal integration of vertically structured programmes. Also suggest credit-linked insurance schemes which can protect resource poor farm families from unbearable risks. Further, suggest methods of strengthening and streamlining the National Horticulture Development Board.

- Suggest measures for enhancing the quality and cost competitiveness of farm commodities so as to make them globally competitive through providing necessary facilities and application of frontier science and promote quality literacy for codex alimentarius standard, sanitary and phyto-sanitary measures among farmers through reorienting and retooling extension machinery. Also suggest methods of providing adequate protection to farmers from imports when international prices fall sharply.
❖ Recommend measures for the credit, knowledge, skill, technological and marketing empowerment of women, taking into consideration the increasing feminization of agriculture and the proposed conferment of right to land ownership.

❖ Suggest methods of empowering male and female members of elected local bodies to discharge effectively their role in conserving and improving the ecological foundations for sustainable agriculture like land, water, agro-biodiversity and the atmosphere with priority attention to irrigation water.

❖ Consider any other issue, which is relevant to the above or is specially referred to the Commission by Government.

The Commission is to submit a mid-term policy for food and nutrition security in the country in order to move towards the goal of universal food security over time within the next three months and to submit its recommendations on other Terms of Reference as the soon as practicable and in any case on or before 13th October, 2006. The Commission, however, is permitted to submit interim reports on any of the Terms of Reference it deemed fit or expected of it.

Composition of the NCF

1. Prof. M.S. Swaminathan … Chairman
2. Shri Atul Sinha … Member Secretary
3. Prof. R.B. Singh … Member
4. Shri Y.C. Nanda … Member
5. Shri Atul Kumar Anjan … Member (part-time)
6. Ms. Chanda Nimbkar … Member (part time) - Yet to join.
7. Shri Jagdish Pradhan … Member (part time)
8. Dr. R.L. Pitale … Member (part-time)
CHAPTER – II

AN INTEGRATED LIFE-SAVING SUPPORT PROGRAMME FOR
FARM FAMILIES FACING ACUTE DISTRESS

The causes of farmers’ distress are many and varied. The dismal growth in agricultural per capita income for decades and the increasing disparities between the agriculture and non-agricultural per capita incomes have meant greater comparative poverty in the rural areas. Inequality in land ownership and technical progress biased against labour compound the problem. The deficiencies in institutional factors, like those related to credit, insurance, supply of inputs like seeds, fertilizers and pesticides and marketing are becoming serious. Prolonged drought and the shrinking production base are other issues. The rigidities of the formal credit institutions and the exploitative attitude of the money-lenders and traders and the weakening of the cooperatives are aggravating particularly the deprivation of the small and marginal farmers and agricultural labour. Compounding the crumbling system of kin, social and institutional support are other factors such as disconnect between research, education and extension organizations, irregular and erratic power supply, land degradation, unsustainable ground water exploitation and successive droughts or other natural calamities. Market uncertainties and imports of farm commodities and economic liberalization have added fuel to the fire.

2. The fundamental cause of the collapse of rural economy is the less than satisfactory performance of the agriculture sector. The low growth in agricultural per capita income is caused by both fast growth of population in rural areas and the relatively slow growth of agricultural and rural output.

3. In the wake of commercialization of Indian agriculture, many small/marginal farmers enter the high risk commercial farming from a position of extreme vulnerability due to meagre asset base and lack of knowledge of technology and familiarity/support for handling the market forces. The cyclical nature of farming with occasional blessings encourages them to take risks much beyond their capacity. When these expectations are not met either due to natural factors or human greed (supply of spurious seeds, pesticides, etc.) or lack of institutional support, these
farmers suffer a great deal. The cycle of distress often starts with increase in borrowings, mostly from money lenders/traders at high rates of interest and with rather unfavourable conditionalities which in most cases lead to further reduction in income, culminating, finally, in loss of land. The farmers are generally in a position to manage one cycle of drought or other distress but are most likely to succumb to it if the cycle was repeated. It is the successive droughts, illness, unexpected large expenses to meet social obligations, collapse of market, a major loss of asset or earning system/capacity which causes severe unbearable distress among the rural people. Public health care systems are very weak in rural area, and expenses related to medical care add to the debt burden.

4. The decline in expenditure on infrastructure in rural areas and reduction in capital formation in agriculture in public sector has meant less wage earning opportunities in agriculturally backward areas leading to overcrowding the labour market thereby further depressing the already low wage rates in these areas. With virtually no specialized skills and limited educational background, the only jobs when and if available to them are manual jobs with low wages. Unemployment leading to out migration of assetless from the rural areas is increasing with resultant stresses and strains. It is also a fact that the income from animal husbandry and wages tend to expand and contract in response to performance of the agriculture sector. In drought years, saving the animal wealth becomes a major issue for the small, marginal farmers and the other poorer households

5. Though the line between the household shocks and the shocks impinging on all the households in an area is not always clear-cut, it is better to distinguish the two. Most of the financial shocks for the households are caused by death/illness/theft/fire, etc. and are expected to be taken care of from the past savings/investments or support from the kin and community. However, with community support system becoming weaker and the vast population existing on the verge of poverty, some financial arrangement to overcome these household shocks are essential. The shocks impinging all people in a large area call for State intervention and relief measures. Besides the short-term measures to deal with specific events leading to distress,
strategies to minimize such events and improving the capabilities of the people to combat such
distress, if they occur, are required to be put in position on a long-term basis.

6. Five sets of action points emerge from the earlier paragraphs:

(a) Immediate relief and rehabilitation measures in the event of disaster impacting a
large area.

(b) A community managed ‘Nutritional Food Security System’ for distress prone
areas.

(c) Enhancing the productivity, profitability and stability of the crop-livestock
farming systems particularly in the ‘distress hot spots’ to begin with. It is
expected that in due course the measures would spread to other areas.

(d) Creation of multiple livelihood opportunities through integrated attention to on-
farm and non-farm enterprises

(e) Introduction of an integrated rural insurance package covering accident, death,
medical expenses and loss to dwelling unit and other property due to
fire/earthquake, etc.

7. It will be appropriate to discuss these in some more detail.

The Immediate Relief and Rehabilitation Measures. In the case of events leading to
distress, the Centre/State Governments often announce special packages to mitigate the
sufferings of the farmers. Some bold and unconventional steps have been taken in the recent
past to mitigate acute distress. While these are helpful, there is need to look at the system to deal
with loss of crops due to droughts and other natural calamities which often take place.

8. While the national/state level capacity to spare and mobilize resources to mitigate the
impact of national disasters has improved, the farm level vulnerability persists particularly in dry
and other fragile regions. The physical, social, economic vulnerability to drought in marginal eco-systems of arid and semi-arid regions is a serious concern. The cyclones in coastal regions and floods particularly in certain parts of eastern India and the north-east do cause considerable distress regularly. The Famine Codes are in existence in India since the British days. After independence, attempts were initiated to change famine relief to scarcity relief. The objective of the new policy was not only to prevent starvation deaths but also the prevention of pauperization of rural population. In some States, Scarcity Relief Manuals replaced Famine Codes. Over time, the approach underwent further changes and the Scarcity Relief Manual/Codes were modified and replaced by Drought Relief Manuals or Drought Hand Books.

9. There is no doubt that the relief and rehabilitation measures have evolved and would undergo further changes as we move from ‘relief’ to ‘management’ approach, the issue will be of the speed and manner in which the relief is delivered to the distressed population. Declaration of Annawari and steps like Remission of Land Revenue which are pre-requisites for the cooperative banks to provide reschedule/conversion of short-term crop loans into medium-term loans take a long time very often defeating the very objective of relief by rescheduling/conversion of loans. The delays in completion of the crop cutting experiments also lead to a considerable delay in settlement of crop insurance claims. There is need for constant updating/revisions on the basis of learnings from field level experiences and also for efficient, transparent and speedy implementation of instructions. There are instances where declaration of drought in certain areas is influenced by political considerations rather than on the behaviour of the rains which leads to building up shades of doubts and uncertainty in the response of financial institutions in particular.

10. **Community Managed Nutritional Security System**: An important step in alleviating human sufferings and building a healthy society would be the establishment of community managed Nutritional Security System with the following components:

   i. Operation of Community Grain Banks, specially in the tribal areas and other far flung areas where Public Distribution System is not effective and efficient
ii. Food for Nutrition Programme on a life cycle basis for pregnant women, infants and old and infirm persons including ‘noon meal’ programme for the school-children.

Community Grain Bank is a tried concept which enables the community to take care of the individual family’s needs in the period of grain shortage. There is a need to cover all tribal villages with Community Grain Banks. To begin with, during 2005-2006 we may plan a target of covering at least 38 out of the 150 districts identified by the Government of India for ‘National Food for Work Programme’ where more than 50% population belongs to SC/ST communities. On the basis of about 25-30 community grain banks in each of the tribal blocks, [villages may be selected on the basis of remoteness, and the proportion of SC/ST families] we could plan about 10,000 grain banks. This should mean a grain bank for every 3-4 villages in the first year itself. The success could lead to more self-help initiatives in other villages. On the basis of 8 ton grain per community grain bank, it would require about 80,000 tons of grains [on the basis of an average price of Rs 5 per Kg the cost would work out to Rs 40 crore]. In addition, about Rs.35 crore may be provided for transportation, storage of grains and formation of grain banks, etc. during 2005-2006. In the subsequent years the coverage could be deepened and also extended to the remaining districts needing this assistance. (A note is at Annexure-I).

11. Enhancing the productivity, profitability and stability of the farming systems: Raising agriculture productivity requires increased investments in human resources, agriculture research and development of efficient and effective extension services, improved information systems, markets, roads and related infrastructure. Better input supply system including credit and power, and larger investments in irrigation systems are also important. Bridging the yield gaps between regions and between the demonstration farms and the farmers fields require no technology revolution but adoption of practices and timely availability of quality inputs. This is important and should get a high priority. For ensuring better profitability and stability, a finely tuned insurance system covering production risks, storage facilities and developed future market in agricultural commodities is needed. For small and marginal farmers in particular, the livestock sector needs better attention and so do the small mechanized tools which could reduce drudgery
and not employment as also the custom hiring facilities to avoid over capitalization. Post harvest handling needs special care and attention to reduce losses and also to improve quality through proper packaging, handling and transportation. Needless to say, an efficient marketing system is important and farmers’ organizations could play a crucial role in ensuring better share to the farmers in the prices paid by the ultimate consumers. The need for food testing laboratories, certifying agencies and a system of dissemination of information about quality standards cannot be over emphasized to build quality consciousness among the farmers to face the future market challenges. Technologies which could reduce the impact of long dry period on crops, enabling the farmers to have a diversified income flow by a mix of crop, horticulture, tree crops, animal husbandry and small micro enterprises would greatly help in stabilizing farmers income.

12. Soil health and seeds need urgent attention. The Government of Gujarat’s decision to have soil health cards for all holdings is a step in the right direction. Application of needed micro-nutrients could increase productivity with a very high cost benefit ratio. Researchers and scientists believe that applying micro-nutrients alone could double or even triple crop yields.

13. At some stage in future, land use may have to reflect the market needs more closely. There have been instances where the farmers have gone in for certain crops where the market was not deep enough to absorb increased production, leading to collapse of prices. A well organized, proactive and efficient Land Use Board could provide valuable advice to the farmers. Seed villages, agri-clinics and one window approach for availability of inputs, technical advice and information are other strategies likely to serve agriculture as well as create additional jobs in the rural areas. The scheme of agri-clinic needs special attention and review because of its potential but rather tardy progress so far. More flexibility and some capital subsidy (back ended to ensure better utilization) could help. Since farmers availing services from agri clinics would have to make payment for extension services which for long have been provided to the farmers free of cost, some government financial support at least during the remainder of the Xth Plan period could help. Once the system stabilizes and more and more farmers develop confidence in the new arrangements, the Governmental support could be withdrawn.
14. **Creation of multiple livelihood opportunities in the off-farm and non-farm areas:** The Government of India have identified 150 most backward districts for implementation of the National Food for Work Programme (NFFWP). The list is attached at Annexure II. It contains Andhra Pradesh (6 Districts), Assam (7 districts), Bihar (6 districts), Chhattisgarh (15 districts), Gujarat (8 districts), Jharkhand (19 districts) Karnataka (4 districts), Madhya Pradesh (20 districts), Maharashtra (15 districts), Orissa (27 districts), Rajasthan (7 districts), Tamilnadu (2 districts), Uttar Pradesh (7 districts) and West Bengal (7 districts). The NFFWP is a very major initiative and would not only reduce the distress of the poor people but would also add to the purchasing power in the rural areas which would stimulate demand for both farm and non-farm products. However, to get the best results the programme may have to be planned very carefully. It would be necessary to select such investments in the 150 districts as would add to productive potential of the area and lead to permanent increase in employment and incomes. The issue of the maintenance of the assets so created would also require to be looked at. Further, the work selection may have to be such as to encourage women participation and benefits. It is also important that these works are planned with due regard to the heterogeneous character of the poor and their uneven distribution in the districts. The identification of the poor, formulation of concrete programme which could lead to increase in productivity, as also provide adequate opportunities to the women and create appropriate organization systems for effective and transparent implementation would require time and effort. The strategy should be to lead to long-term benefits for the poor and not just the short-term transfer of resources.

15. **Improving access to institutional credit.** Credit is an important input. In India, the State has always shown concern and involvement in rural credit particularly agriculture credit. At the time of independence, institutional credit support for agriculture was nominal and bulk of the requirements of the farmers were met by non-institutional agencies. The Rural Debt and Investment Survey 1951 revealed that 92.7% of the rural household debts were from the money lenders (69.7%), traders (5.5%), landlords and others (3.3%) and relatives and friends (14.2%). The Cooperative Banks (3.3%), the Commercial Banks (0.9%) and the Government (3.1%) provided the institutional credit support aggregating 7.3% of the total. The Government took many measures like the nationalization of private commercial banks, liberal and concessional financing of the cooperative banks by RBI/NABARD, establishment of NABARD, fixing
priority sector/agriculture sector lending targets for commercial banks, establishment of 196 Regional Rural Banks (RRBs) and introduction of crop insurance and by 1991 the share of institutional credit had increased to nearly 66.3% of the total indebtedness.

16. During 2003-04, the banks provided nearly Rs.80,000 crore as agriculture credit. The Union Government wants the credit flow for agriculture to double i.e. reach a level of Rs.1.60 lakh crore by 2006-2007. For 2004-05, a growth of 30% has been envisaged and the credit flow during the year is targeted to reach Rs. 1.05 lakh crore. A series of measures have also been taken/are being taken to reach the above level. The UPA Government is also committed to nurse the rural credit system back to health. It is expected that measures to revitalize the cooperative credit system linked to a reform agenda is also likely to be announced. In view of the initiatives being taken by the Union Government and the recently submitted Prof. V.S.Vyas Committee Report, we could expect considerable acceleration in flow of rural credit and improvements in quality lending.

17. A notable development during the nineties has been the improvement of the outreach of the banking system through linking of the Self Help Groups (SHGs) to the bank branches. By March 2004, nearly 10.79 lakh SHGs had been linked to the banks. During 2003-04, the banks provided an aggregate of Rs.1855.53 crore as loans to the SHGs. There is no doubt that the SHG-Bank linkage programme has contributed substantially to the feminisation of ‘micro finance’ banking in India. The members of the SHGs are those people who were earlier bypassed by the banking system and are poor. Incidentally, the SHG-Bank linkage is the largest and the fastest growing micro finance outreach programme anywhere in the world.

18. This approach has enabled 1.67 crore poor families to have access to financial services including credit and has generally helped in increasing their incomes/work days.

19. Keeping in view the success of the programme, it is suggested that NABARD/Banks may make further efforts to deepen the programme particularly in the 150 identified districts for wage employment programme. The approach should be to saturate these districts with SHGs and give
a very large coverage to the rural poor under the programme and thereby improve their access to financial services. According to a NABARD publication, ten out of these 150 districts do not have SHGs linked to the banks. These districts are Jaspur, Korba, Koria (Chattisgarh State), Dangs (Gujarat), West Nimar, Umaria, Sidhi, East Nimar, Katni (Madhya Pradesh) and Phulbani (Orissa). The approach could be to make special efforts to broaden the programme to cover the above ten districts and deepen the programme in the remaining 140 districts on a priority basis. It is also worth noting that in as many as 50 out of the 140 districts, the spread of the SHGs linked to the banks is very thin in as much as the number of SHGs linked to the banks is less than 500 in each of these districts.

20. By broadening and deepening of the SHG Bank Linkage Programme in the above 150 identified districts, these groups could provide an effective mechanism for the public and private sector agencies to reach them and extend support to enable them to strengthen their livelihood security through additional on-farm, off-farm and non-farm activities. The private sector could play an important role by helping to provide assured and remunerative marketing avenues for the products of the SHG members.

21. Insurance- A financial product to mitigate the sufferings: Crises are recurrent in the lives of the poor. These crises, caused by personal, social or certain natural disasters usually need large expenditure to tide over and lead a poor family deeper into poverty. The range of crises is large. The common among them are accidents, hospitalization, death in the family, death of the bread winner, loss of crops or assets and natural calamities like droughts, floods, cyclones. Expenses to be met during these crises are met either by drawing on savings/investments, borrowings or sale of assets, etc. Institutional arrangements for meeting such expenditure is virtually not in existence and unless relatives/friends agree to help, money lender/traders provide the facilities but at terms and conditions which are generally exploitative. The household suffers an increase in debt/liabilities, increase in expenditure (debt service) and reduction in income. It leaves the poor weaker and more vulnerable, ultimately leading to loss of land.
22. Insurance is a financial product that could help the poor in the event of crop loss, cattle loss, accident, death of the insured, hospitalization charges and loss of insured asset by pooling the risks and distributing the costs among a larger number of people. So far the insurance market in India is concentrated in the urban middle and upper income groups. With a view to improving the penetration into rural areas the Insurance Regulatory and Development Authority (IRDA) has stipulated that a certain minimum fixed percentage of the total business should come from the rural sector.

23. While the need for insurance as a financial product for covering the risks is well established, the issues are the low level of awareness about insurance as a financial product for mitigating various risks which the rural people have to face, the inability of the poor to pay insurance premium upfront, low premium incomes and high service cost of the insurance companies and the absence of an effective network of insurance agents in a perceived low potential rural area. Insurance products for rural areas would have to take care of the above issues. It is obvious that small valued insurance policies could mainly be sold to groups, as individual sales would be uneconomical. Further, it would also facilitate both the insured and the insurer if the premium amount was built into a loan component which the insurer could repay in appropriate instalments either with other loans or independently. Lastly, if the banks or other people’s structures could be involved it would minimize the need for traditional agent net-work and also add a little income/incentive to those organizations. At present mainly the crop loss and loss of livestock and other assets purchased with institutional credit are largely covered by insurance in rural areas.

24. While the general insurance covering risks mentioned earlier is feasible with linkage to bank credit, the life cover which is normally a savings/investment option with risk cover may not be feasible with credit linkages which are in the nature of short-term or at best medium-term arrangements. However, efforts may have to be continued for development of suitable product with endowment after three/five years along with providing the risk cover. There is need for innovation and developing different products for meeting the requirements of the rural population keeping in view their income flows and risk perceptions. However, the product may
have to be simple and attractive. But for the present, it may be appropriate to make a beginning with general insurance of risks encountered by farmers in their daily life including the cover for death. However, that part of the premium which covers ‘life’ will have to be passed on to the specialized institutions dealing with life insurance. Other covers including accident leading to physical injury or death could be handled by the organisations permitted to deal with general insurance.

25. Insurance cover requirement of the farmers and others in the rural areas are mainly for crop loss, asset loss, loss/damage to the dwelling place, accidents causing physical loss/loss of life, medical expenses, natural death etc. These are discussed below in detail.

Crop Insurance

26. The first and foremost risk of the farmer is the crop risk. The risk of crop failure is being met under the National Agriculture Insurance Scheme (NAIS) which is being implemented through the Agriculture Insurance Company of India Ltd. The scheme is presently being implemented by 23 States and 2 Union Territories. The scheme covers food crops and oilseeds, annual commercial/horticulture crops. The premium rates for food crops and oilseeds range from 2.5%-3.5% during Kharif and 1.5% - 2% during Rabi. The rates for annual commercial crops are actuarial. The scheme operates on area approach for widespread calamities and on individual basis for specified localized calamities. However, individual assessment of losses is experimented only in a few areas.

27. The small/marginal farmers are subsidized in premium to the extent of 50% to be shared equally by the Centre and States. The subsidy is proposed to be phased out over a six year period. Accordingly, the eligible subsidy is 10% during 2004-05. The scheme covers all farmers (compulsory for loanee farmers and voluntary for non-loanee farmers). The scheme is open to all States/Union Territories on optional basis. A State opting for the scheme will have to continue for minimum three years. The States which are not covered are Punjab, Arunachal Pradesh, Manipur, Nagaland and Mizoram.
28. Till Kharif 2003, the NAIS covered 4.18 crore farmers for a premium of Rs. 1,179 crore and finalized claims of Rs. 4,473 crore. During 2002-03, 102.97 lakh farmers were covered for a sum of Rs. 9,951 crore and the premium collected was Rs. 321 crore. According to available data, claims costing Rs. 810 crore were settled benefiting nearly 26 lakh farmers.

29. In addition to the above, the Government of India is also implementing a Farm Income Insurance Scheme (FIIS) from Rabi 2003-04 in 19 districts in 12 States on a pilot basis for Rice and Wheat. The Scheme covered 1.8 lakh farmers for a sum insured of Rs. 241 crore. The FIIS is also based on an area approach and provides income guarantee based on the ‘Minimum Support Price’ (MSP). If the actual income \[\text{Current yield } \times \text{ current market price}\] is lower than the guaranteed income \[\text{Average yield of 7 years } \times \text{ the level of indemnity i.e., 80% or 90% as the case may be, } \times \text{ MSP}\] the insured farmer is compensated. The premium rates are actuarial with 75% subsidy to small/marginal farmers and 50% to others. The scheme was extended to Kharif 2004 season, and was implemented in 19 districts of four States for Rice. The scheme is rather new and is being tested on a pilot basis.

30. In addition to the above, weather insurance scheme covering anticipated shortfall in crop yield on account of adverse weather parameters has been introduced recently. All individuals who stand to lose financially on account of adverse incidence of weather could take insurance. The advantages of weather insurance are as under:

(a) The trigger events like adverse rainfall, temperature, moisture, relative humidity etc can be independently verified and measured.

(b) It allows for speedy settlement of indemnities as early as a fortnight after the indemnity period.

(c) It could be implemented for all crops with little historic yield data.

(d) Problems of adverse selection and moral hazards could be controlled to a large extent.
(e) All cultivators and other people who are dependent on agriculture, could be covered.

(f) Wide choices of payment options could be provided commensurate with premium.

(g) The scheme is easy to operate and understand.

31. The weather insurance (Varsha Bima) was launched on a pilot basis in 20 rain guage areas of Andhra Pradesh, Rajasthan and Uttar Pradesh during Kharif 2004. It is likely to be expanded to about 100 districts in Kharif 2005. There is a great potential for extending the coverage of the scheme.

32. While the crop insurance scheme, the NAIS is in operation since Rabi 1999-00, there is a lot of criticism about the delay in settlement of claims, the basis of settlement and the need to switch over to a smaller ‘defined area’ from Block or Tehsil to Panchayat etc. Further, the scheme has primarily covered the loanees of banks. Substantial number of farmers who have no access to crop loans from the banks and raise money from non-formal institutions are virtually out of the scheme. The awareness level about the crop insurance, its rationale and advantages have not been adequately disseminated. Even the loanee farmers who are covered by the crop insurance are taking the cover not because of its perceived usefulness to them but because it is compulsory. Considerable work in building awareness, getting feedback and developing appropriate products needed by the farmers was perhaps necessary. In Gujarat, a study done by the Disaster Mitigation Institute in 3 districts of Patan, Kutch and Surendranager, revealed that nearly 40% of the farmers were not aware of the Crop Insurance Scheme (the coverage of crop insurance is high in Gujarat; during Kharif 2003, out of nearly 80 lakh farmers taking crop insurance in India, nearly 10.16 lakh i.e. about 13% were from Gujarat alone). It would appear that realising the need and importance of broad basing the crop insurance programme and to make it more farmer friendly, the Government of India have recently constituted a Joint Group under the Chairmanship of Additional Secretary (Ministry of Agriculture) to review various aspects of crop insurance. The Group would consider improvements in crop insurance particularly the NAIS. The Group is likely to submit its report shortly.
33. In view of the above, we may await the report for needed improvements in the crop insurance scheme. However, it is necessary that the scheme be more farmer friendly. It may cover more crops, the farmer may have the option of seeking higher compensation, the settlement may be much quicker and the area as the basis for assessing the crop loss may have to be much smaller than what it is now.

34. **Cattle Insurance**

Cattle risk is another significant risk for the rural people. The animal husbandry sector contributes nearly 23% of the agricultural GDP. Cattle provides much needed diversification of farmers’ income as also a regular cash inflow against income from crop which is seasonal. The total value of milk group to the economy is nearly 1.5 times the total value of paddy and nearly 2.4 times the value of wheat. Further, ownership of livestock is more evenly distributed than land. However, it may not be possible to cover cattle in the integrated insurance product. There would be different breeds, age group, sex and quality and number of animals with individuals in a group which would attract different insurance premium. The general premium for cattle insurance is around 4% while milch animals financed under ‘schemes’ are covered at a subsidized rate of 2.25%. While there is no doubt about the importance of livestock, insurance for the farmers, for the time being, may have to be mainly on individual basis. However, the implementation of the cattle insurance as it obtains now, does not satisfy the farmers much. The procedure for verification of claims and their settlement is a source of constant irritation and subject of many jokes. This calls for a relook.

35. This brings us to other risks, i.e.; the accident risk, loss/damage to dwelling and property, natural death and medical cover. It is possible to cover these with an integrated product. However, considerable effort is required for building up awareness about the utility of insurance products. It appears that many in the rural areas are driven to extreme poverty and distress due to illness, loss of income due to injury by accident, etc. Risks to health are frequent and generally have a serious impact on the welfare of the family. It reduces their incomes and increases the expenses. This would mean borrowing from the moneylenders at very high interest rates leading to ultimately loss of assets and land. It is also a fact that the rural medical facilities are not
adequate and the people have also to spend money on transportation/meals, etc. The same may therefore have to be built into the insurance product. It would be ideal if an effective third party administration system could be developed for medical coverage, where the lists of hospitals could be firmed up with uniform charges for different surgical interventions as also other treatments. In this system, the insured could get the treatment and the bill to the extent of the insurance cover directly settled by the third party administrator (TPA) system. The insured would be required to make direct cash payment for only the excess amounts (over and above the ceiling of the cover) if any. However, in absence of such arrangements on an all India basis and the need to extend medical insurance urgently, it may be useful to introduce cover for hospitalization charges to start with. Incidentally, the Common Minimum Programme of the United Progressive Alliance has mentioned that a national scheme for health insurance for the poor families would be introduced. The efforts may, however, be continued to have a TPA system all over the country at the earliest. It is also expected that with the coverage of large number of people under the scheme and the involvement of the SHGs/other peoples’ structures/NGOs and Banks, there would be strong pressure on the health services and insurance companies to improve their products and become more user friendly than what they are today. The TPA/Insurance Companies would, in their own interest, make efforts to improve ‘preventive’ systems and practices and also negotiate with rural health service providers to reduce costs and improve services. Another issue is the poor spread of the rural health services. It may be useful to encourage establishment of private nursing homes/hospitals and Voluntary Health Services in the rural areas by providing tax benefits, concessionality in the credit /back ended subsidy etc. They should provide low or no cost healthcare of high quality. The large expansion in demand for ‘paid’ health services under insurance cover is expected to be seen by the private health service providers as a huge expansion of the market and incentive for them to reach the rural areas.

36. There has been a recent development in the micro insurance sector. The Insurance Regulatory and Development Authority [IRDA] has issued instructions regarding issuance of license to the NGOs/SHGs for working as agents for accepting insurance proposals upto a sum assured of Rs.10,000. The NGO/SHG would be entitled for commission on this work and the qualification/training requirements for issuance of license to them have also been kept low. In
view of the above, it may be appropriate to devise a suitable product which could be canvassed by the NGOs/SHGs to their members.

37. The cover could be floating for different insurance risks. The product could be as under:

A. The integrated Insurance Policy for the poor – through the Self Help Groups etc. could cover:

(i) Dwelling and household assets (excluding jewellery and valuables) against fire, allied perils and earthquake for Rs.10000/- and Rs.5000/- respectively. In case of ‘hut’ the sum insured would be Rs.4000 for the dwelling unit and Rs.1000 for the contents.

(ii) Personal cover against accidental death, permanent total disability and permanent partial disability, the sum insured would be Rs.10,000/-.

(iii) Mediclaim insurance in case of hospitalization – benefit upto Rs.10000/- for husband, wife and two dependant children on floater basis including sums not exceeding Rs.200/- for transportation and Rs.150/- for meals during the policy period.

(iv) Natural death of the insured male or unmarried/widowed woman and husband in the case of married woman – Rs.5000/.-.

The premium could be around Rs.225 to Rs.300/-p.a (the exact premium however have to be ascertained from the insurance companies). This product could be called ‘Parivar Bima Policy’.

B. Another product could be with higher cover [aiming mainly at the KCC holders] as under:
i) Building and household contents (excluding jewellery and valuables) against fire, allied perils and earthquake for a sum of Rs.30,000/- and Rs.10,000/- respectively.

ii) Personal cover against accidental death, permanent total disability and permanent partial disability for a sum of Rs.50,000/-. 

iii) Mediclaim insurance for Rs.30,000/- on floater basis (applicable to any of the five members) with a cap of Rs.15,000/- per illness. The premium for this coverage is Rs.548 with exemption from service charges. It is exactly the same as ‘Universal Health Insurance’ introduced by the Government of India for below the poverty line (BPL) families with a subsidy of Rs.300/-. 

The annual premium would be around Rs.575 (the exact premium however have to be ascertained from the Insurance companies).

38. The choice of policy could be left to the individual/group. However, if the policy is covered under micro insurance, it would have to be limited to Rs.10,000 only. In all the cases, loan could be included/advanced for the insurance cover and recovered along with other loan or as per instalments etc.

Need for special developmental efforts/support for integrated Insurance products.

39. Insurance is an essential financial product and together with facilities for deposits and credit constitute the major financial services required by the people. While micro finance has got lot of attention during the last decade or so the emphasis has been mainly on thrift and credit. Micro or even rural insurance (excepting crop insurance or insurance of cattle and other assets financed by the banks) has not made much progress. There is also a need for engendering the insurance system which so far has mainly covered the male population. Besides the issues of low value covers, high transaction costs, problems connected with servicing of individual clients who are scattered and lack of traditional network of agents and moral hazards, the other issues are
building up the confidence and awareness of the rural population about the insurance products, designing appropriate products and innovations in delivery system to popularize them and the ability of the poor to buy insurance cover which they need most but are unable to afford. There is a developmental role for the insurance companies, the IRDA, the banks and the Government particularly about building up awareness of the rural population and convincing them about settlement of claims without too much procedural delays and form filling.

40. As a part of providing safety net to the very poor, the Government may consider meeting part of the premium at least during the remaining years of the Xth plan period. The position could be reviewed thereafter. The crop insurance has been financially supported for quite some time for all farmers. The Government of India have also agreed to provide support to the tune of Rs.300/- (out of a premium of Rs.548/-) for ‘Universal Health Insurance’ for BPL families. Subsidy of Rs.200 out of a premium of Rs.365 if the coverage is only of one person in the family and Rs.400 against a premium of Rs.730 if besides the family of five (as in Universal Health Scheme) the parents are also covered. It would, however appear that in the absence of proper delivery arrangement and developmental efforts, the scheme has not made much headway.

41. The insurance products listed earlier have a potential of reaching about 2 crore poor families mainly through the SHG route in 2-3 years and another about 4 crore Kisan Credit Card holders in the same period. In other words, there is potential to cover upto half the rural families in the country by 31st March 2007. Incidentally, since around 90% of the SHG members are women, the coverage would also contribute towards engendering the insurance system to a certain extent.

42. If the ‘Universal Health Insurance’ cover had been extended to about one third of the BPL families (about 2 crore families) the annual support would have worked to around Rs.600 crore per annum. However, the scheme has not made much progress perhaps because of inadequate attention to the delivery system and special efforts essential to popularize a new product could not be made. It would be necessary to have a National Level Steering Committee to look into the progress on a regular basis. The Committee could have representatives from
Govt. of India (Deprt. of Banking & Insurance and also Ministry of Health), IRDA, the National Commission for Women, NABARD, IBA, National Agriculture Insurance Company, all the four general insurance companies, SBI, NASCOB (Federation of State Cooperative Banks) and one/two representatives of the RRBs. The National Agriculture Insurance Company could provide the secretarial assistance and house the Committee.

43. In order to encourage resource poor families to take up the cover, the GOI may support the scheme which is really a life saving support to the rural poor. The premium could be shared by the GOI and the insured people in the ratio of 1:1 in the case of Scheme-A of micro insurance i.e. the Parivar Bima Policy and at the present rate under the Universal Health Insurance Scheme for the BPL families covered under the Scheme-B. For non BPL families, covered under Scheme-B a token support of Rs.100 may be provided. If about 1.5 crore people take up Scheme-A (Parivar Bima Policy) through the SHGs etc during 2005-06, the life saving financial support would work out to about Rs.169 crore on the basis of 50% of the likely premium of Rs.225 and for Scheme-B, assuming about 5% of KCC holders are BPL, i.e., about 20 lakh KCC holders, the support (average taken at Rs.300) would be around Rs.60 crore and for non BPL families assuming about 30 lakh people take the cover would work out to another Rs.30 crore. The total would be Rs 259 crore or say Rs.260 crore.

45. A Rural Insurance Development Fund of Rs.50 crore may also be created at the National Agriculture Insurance Company to take up development work for spreading rural insurance. The Standing Committee referred to earlier could also be asked to frame guidelines for use of the Fund.
COMMUNITY GRAIN BANKS

Community Grain Golas (Banks) are an age old concept in the villages particularly the tribal villages. The entire community contributes grain to the ‘Gola’ from which any family could draw the grains at the time of need and return the same with an additional quantity representing ‘interest’ at the harvest time. This provided nutritional security to the poor families particularly during the ‘Monsoon’ period when there were no work opportunities in the villages and going out in search of employment outside the village or in the forests for collecting minor forest produce was not feasible. One should also bear in mind that a large number of villages, particularly the remote tribal villages, do get cut off during rains making it difficult for the villagers to go out or the supplies to reach them. This period also often coincided with depletion of the saved grains from the previous harvest making nutritional security a serious issue for below the poverty line population and more particularly the children, infants and pregnant and lactating mothers.

2. Grain Golas are a community self-help system which could go a long way to provide nutritional security to the poor tribal families. Under an on-going scheme, the Government is assisting in the formation of Grain Golas in the tribal areas. The idea is to cover all the tribal villages (about one lakh) in due course. The target for 2004-05 is however only 3500 grain banks. According to the TRIFED data, between 1996-97 to 2003-04, money has been released (Rs.20.50 crore) for establishment of 4858 Grain Banks in 11 States viz. Andhra Pradesh (905), West Bengal (152), Bihar (61), Gujarat (237), Madhya Pradesh (2461), Orissa (662), Tripura (78), Rajasthan (33), Tamil Nadu (2), Kerala (2) and Maharashtra (259). No Grain Bank could be established under the Scheme in Uttar Pradesh and Manipur which were also covered under the programme. The coverage of these grain banks is about 3.50 lakh families. Incidentally, nearly 62% of the Grain Banks were supported in 2002-03 and 2003-04 and about 83% of these were in the three States of Madhya Pradesh, Andhra Pradesh and Orissa.
3. Under the Scheme 100 qtls of grain for 100 families @ 1 qtl per family (the total quantity of 100 qtls is fixed regardless of families) is provided, along with Rs.2000 for weights/balance and Rs.2000 for storage bins, etc.

4. The cost of transport is met by the Centre and the State Government at 1:1 ratio.

5. It is understood that the scheme is under revision in the following respects:-

   (a) The scheme would be available to all BPL families

   (b) The main focus would be on endemic drought and migration prone tribal concentration areas. The non-tribal areas to be included later.

   (c) The allocation of grain would be @ 2 qtls per family and for an average Grain Bank covering 40 families, 80 qtls of grain would be supplied.

   (d) In addition the Grain Banks would also be given Rs.5000 for weights/measurements/storage bins, etc.

   (e) A training support of Rs.500 would also be provided to the NGO promoting each Grain Bank.

   (f) 50% of the transportation cost would be borne by the concerned State Government.

6. In order to encourage self-help and make the Grain Banks sustainable, it is suggested that:

   (a) The Government may consider whether it would not be better to release only 50% of the grain in the first instance and balance on a matching basis with the grain saved/increased by the Grain Bank
(b) The NGO assisting in the formation of a Grain Bank may be given at least Rs.2500 for establishment of each grain bank and another amount of Rs.1000 after one year of the establishment provided the Grain Bank is operating successfully and has collected additional grain from members by contribution/interest-charged which is not less than 50% of the grain initially given by the Government. It is felt that the proposed provision of only Rs.500 for training for each Grain Bank is far too inadequate. The remote tribal areas which would be initially selected, would pose serious problems of transport and communication and hence the NGOs taking up the responsibility of the formation of the Grain Banks need be compensated for their expenses and efforts. Payment of additional Rs.1000 if the grain bank develops would serve as an incentive to the NGO to focus on this area and develop sustainable Grain Banks.

(c) The sum of Rs.5000 for weights/measures/storage bins, etc. as proposed under the scheme appears to be inadequate. Storage bins for storing about 8-10 tons of two different types of cereals may cost more. According to the Indian Grain Storage Management and Research Institute, Hapur, the estimated cost for a 12 tons grain storage with inlet and outlet made of RCC sheets was around Rs. 22000 (2002 estimates). A storage built with reinforced bricks (RBs) with a capacity of 6.68 ton would cost around Rs.24000. It is suggested that an average estimated cost for each Community Grain Bank for storage, weights and measurements, etc. may be placed at Rs.25000.

(d) Instead of spreading the scheme thinly in a large number of States/districts, the Government may consider saturating the districts which have at least 50% of the populating belonging to the ST and SC categories. In 150 districts identified by the Government of India for employment guarantee scheme, there are 38 districts where the tribals and the Scheduled Caste constitute at least 50% of the total population. The list of these districts is attached (Appendix A). During 2004-05, the programme could be to set up 10,000 Grain Banks in the above districts i.e. about 250-275 grain banks in each district.
7. Besides, the cost of grains, the other costs for 10,000 community grain banks would be as under:

<table>
<thead>
<tr>
<th>(Rs. in crore)</th>
</tr>
</thead>
<tbody>
<tr>
<td>a) Cost of formation @ Rs.2500 each &amp; incentive @ Rs.1000 each</td>
</tr>
<tr>
<td>b) Cost of Weights /Measures &amp; Storage arrangements @ Rs.28000 each</td>
</tr>
<tr>
<td>c) Transport @ Rs.90/- p. qtl. 50% i.e. Rs.3600 per grain bank</td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

As regards the cost of grains, on the basis of an average Rs.5/- per Kg. the total cost would work out to Rs.40 crore. Thus the total outlay would be about Rs.75.1 crore or say Rs. 75 crore.
## APPENDIX – A

CHAPTER - III

PRODUCTIVITY AND LIVELIHOOD ENHANCEMENT IN RAINFED AREAS

Towards a Rainbow Revolution:

The greatest distress to farm and rural communities occurs in areas with low and uncertain rainfall. These areas occur mainly in the arid and semi-arid regions of the country. The people living in such environmentally underprivileged areas have over centuries developed methods of coping with natural calamities. Migration with their cattle or sheep was one common method of withstanding the problem of water, food and fodder shortage. Women often stayed behind and had developed fairly effective methods of saving whatever rain water became available and shared it equitably. Anil Agarwal and Sunita Narain\(^2\) have documented such “dying wisdom”. As early as 1925, the Royal Commission on Agriculture emphasized the need for developing technologies which can help to elevate and stabilize crop and livestock production in dry farming areas. After independence, several collaborative projects were undertaken in the field of dry farming, like the Indo-French project in Anantapur district, the Indo-UK project in Indore and the Indo Canadian project all over India. National and international research efforts were strengthened and an International Centre for Research on Semi-arid Tropics (ICRISAT) was established in 1972 at Hyderabad. Inspite of the very valuable work done under these projects, the fate of farmers in rainfed areas continues to remain a gamble in the monsoon.

2. Covering 66% of the cultivated area, rainfed farming continues to be critical for meeting the livelihood needs of a vast majority of small, marginal and tribal farmers in the chronically drought prone areas of the country. Despite the development of new technologies related to crops, resource management, livestock and fisheries during the last 3-4 decades, the farm level adoption and impact on the farmers’ income and livelihood in these disadvantaged areas has not

---

been as significant as in irrigated areas. This is mainly due to the low and highly fluctuating productivity and the low risk bearing capacity of the rainfed farmers, for whom risk aversion is more important than productivity enhancement. Low rainwater use efficiency and the constant threat of water scarcity and drought aggravate the situation. Land degradation and declining soil health, acute fodder shortage and poor livestock productivity are the other serious constraints. These challenges are further compounded by a large number of institutional, policy and infrastructural constraints, like lack of assured and remunerative marketing opportunities.

3. Though rainfed agriculture has remained a high priority area through all the Five Year Plans, the UPA Government has identified this area as one of the key priorities to address the problems of poverty, food insecurity and regional and gender inequity. Accordingly, 150 most backward districts in the country have been identified, a majority of which are rainfed. Any improvement in the livelihood of the farmers and landless labourers in these areas is intimately linked to the progress achieved in rainfed agriculture including horticulture, agro-forestry, livestock, poultry and all related farming systems. A Rainbow Revolution is needed for achieving congruent and synergistic improvement of all the components leading to enhanced and sustainable agricultural productivity and profitability and strengthening of livelihoods through eco-technologies, diversification, value addition, and work security.

**Strategic Paradigm Shifts for Converting Potential into Production**

4. In order to bridge the prevailing income and livelihood divides and to break the nexus of poverty, food insecurity and natural resource degradation, the following strategic paradigm shifts are suggested.

4.1 Foster and build convergence and synergy among components of development, interventions and stakeholders – public-private-corporate-NGO-CSO-farmers, and leverage the potential of small farmers and landless labourers, including women, through group actions and institutions.
4.2 Undertake area-based actions for wet, dry and semi-arid rainfed areas by involving the active participation of grass root communities through Panchayats and Gram Sabhas, engendering the transformation process, and meeting the needs and potentials of rural people – farmers, landless agricultural labour and artisans, using a disaggregated and differentiated approach.

4.3 Move from commodity to farming system approach to integrate crop, horticulture, livestock, aquaculture through development and adoption of system based eco-technologies rooted in the principles of inclusiveness, environmental sustainability and economic viability.

4.4 Build capacity through knowledge empowerment in areas relating to weather, water, pest management, post-harvest technology and home and external markets.

**Convergence through Watershed Development**

5. Integrated watershed management is the most proven approach for increasing productivity and strengthening livelihoods. Recent study jointly conducted by ICRISAT and International Water Management Institute (IWMI) involving 311 watershed programmes in India showed that the mean benefit cost ratio of watershed programme in the country is 1:2.14 with an internal rate of return of 22% which is comparable with many rural development programmes. The watershed program had generated new employment opportunities, augmented irrigated area, enhanced cropping intensity and better conserved soil and water resources (Box. 1).

6. The demonstrated success of the above mentioned watersheds and a few other watersheds in the country notwithstanding, the success has not been as pervasive as desired. In general, the following problems have been identified as major bottlenecks in implementing watershed programmes: (i) multiple funding sources and guidelines and top-down approach of priority setting, (ii) compartmentalization, lack of coordination and monitoring, (iii) diversion of funds to unrelated uses, (iv) limited community participation, specially of women, (v) unsustainability of the gains and low build up of asset and (vi) less focus on landless and non-agricultural groups.
An innovative farmer participatory watershed development model with consortium for technical backstopping

International Crops Research Institute for the Semi-Arid Tropics (ICRISAT) in partnership with Central Research Institute for Dryland Agriculture (CRIDA), National Remote Sensing Agency (NRSA), State Agricultural Universities, State Government Departments, Non-Government Organizations and Farmers Associations/Organizations have developed and tested an innovative integrated watershed development model for enhancing the productivity of rainfed agriculture, minimizing land degradation and improving the livelihoods. The pilot model was developed and evaluated in Adarsha Watershed at Kothapally in Shankarpally Mandal in Ranga Reddy district of Andhra Pradesh. The main components of the participatory consortium approach for community watersheds are:

- Farmers collectively identify and prioritize the problems for possible technical interventions, participatory planning and implementation of watershed development involving all the stakeholders.
- A consortium of research and development organizations including NGOs provided technical backstopping to community watershed programs.
- Increased individuals participation is ensured by providing tangible economic benefits through in-situ water conservation of rainwater which is translated into increased productivity and incomes through integrated genetic and natural resources management (IGNRNM) approach. Holistic systems approach for watershed management for livelihood improvement in place of compartmental approach adopted earlier.
- Knowledge flow is facilitated by linking successful on-station watersheds and on-farm watersheds for strategic research.
- Islanding approach is used in which a strategic research watershed is established within the macro-watershed/district to serve as a site of learning.
- Cost effective and environment-friendly soil, water, nutrient, crop and pest management practices for wider adoption to raise the carrying capacity of the system.
- Empowerment of communities, individuals and the strengthening of the village institutions is achieved for sustainable development.
- Continuous monitoring and participatory evaluation by researchers and elimination of contractors for implementing the works increased transparencies, over all performance and sustainability of the program.

This approach resulted in substantial reduction in runoff volume (29% less than untreated area), significant reduction in soil loss (only 1/3) was found from treated compared to untreated watershed. Increased groundwater availability in the watersheds resulted in reviving of dead open wells and additional 55 new borewells were dug during the project. Due to additional groundwater recharge, 200 ha area were irrigated in post-rainy season and 100 ha in summer season growing vegetables and other high value crops. Mean average raised groundwater was 415 cm during 1999-2001. With improved technologies, farmers’ crop yields are increased by 2.2 to 2.5 times for maize, sorghum, chickpea and up to 4 times in case of pigeonpea. Income of individual households was substantially increased and the net returns on rainfed cereal crops were more than double as compared to the non-watershed village and also with the baseline incomes in 1998. Average household income from crop production activities within and outside the watershed was 15,400 and 12,700 respectively. The respective per capita income was 3,400 in the watersheds and 1,900 outside watershed. This resulted into significant impact of watershed interventions towards poverty reduction in the watershed through increased incomes for the poor from crop production activities.

ICRISAT led consortium has scaled-up this model in 200+ watersheds with the funding from Sir Dorabji Tata Trust, Andhra Pradesh Rural Livelihood Program of Government of Andhra Pradesh supported by DFID. U.K. and with Asian Development Bank in states of India (Gujarat, Madhya Pradesh, Andhra Pradesh, and Rajasthan) and parts of north-east Thailand, northern Vietnam and South China. The results during the last 2 years have clearly demonstrated that this model could be scaled-up and the productivity of rainfed agriculture along with incomes were substantially improved while minimizing the land degradation in the rainfed areas. For scaling-up the benefits from the pilot 200 villages necessary details of linkages, institutions, policies are being worked out. This holistic innovative model has changed the paradigms for watershed management in India where watersheds are used as an entry point for improving the livelihoods and protecting the environment. Main success of the model depends on implementation of participatory approach by the community, empowerment of the stakeholders, building the available institutions and community-based organizations and most importantly technical backstopping by the consortium.
Major Pathways to Productivity and Livelihood Enhancement:

A. Public Policies:

7. **Convergence and synergy:** There is a need to achieve convergence and synergy among all the dryland farming and watershed programmes in India. For this purpose, we suggest the setting up of a **Commission for Sustainable Livelihood Security in Dry Farming Areas** under the Chairmanship of an eminent farmer. Appropriate counterpart bodies at the State, district and watershed (local) levels should also be constituted.

8. **Technology:** In the watershed development projects technical backstopping is lacking and hence 15% of the developmental project budgets could be earmarked for on-farm strategic research to ensure refinement and incubation of new technologies in the developmental programmes.

9. Fortunately, we have excellent national and international research institutes like Central Research Institute for Dryland Agriculture (CRIDA) and ICRISAT in Hyderabad, which have rich technical knowledge in elevating and stabilizing the yield of dryland crops. The Commission for Sustainable Livelihood Security should take full advantage of the vast pool of unutilized knowledge available in research institutions/Agricultural Universities.

10. **Empowering the grass root institutions:** Empowerment of community based organizations (CBOs) and Panchayati Raj Institutions (PRIs) is critical and special measures to augment the technical expertise at PRI level need to be done through appropriate policies and resource allocation. The development work in the district can be taken through PRIs effectively utilizing the existing infrastructure present in various line departments associated with development of rainfed areas.

11. **Establishing R&D consortia:** All development programmes for the rainfed areas should have technical backstopping through a district level R&D consortium of organizations, which should include the relevant experts, development agencies, women’s groups, farmers, private
sector companies, financial institutions and other stakeholders. The consortium is designed to bring the best available scientific know-how and crop varieties to farm families.

12. **Flow of Funds:** Funds for development work, as shown below, can go directly from the Commission to the district and from district to the PRIs. For strategic and applied research, the total fund designated for the purpose may be passed on to the research organizations implementing the project. The development part of fund can be channeled through the project to the PRI.

13. **Enhancing investment in rainfed areas:** Several studies in India and elsewhere have shown that the economic returns to investment in rainfed areas, specially in research and technology development, is much higher than that in irrigated and congenial areas, let alone the gains in environmental health and agro ecological security. Therefore, it is heartening that the UPA Government is giving high priority to rainfed areas, which should enhance effective investments in these areas. Recognising that development of technologies like IPM, IRM, INM, biotechnological alchemy of bio-resources and other system based technology developments are much more costlier than the technologies designed for single commodities and based on single discipline, the enhanced investment in rainfed agricultural research and technology development should particularly be given high consideration. About 10 percent of the total investment in watersheds should be allocated for rainfed research and technologies.
14. **Enhancing the Social Capital and Insulating Farmers from Risks:** Investing in the social capital in the risk prone rainfed areas is equally important, if not more, than the monetary investment for creation of physical assets. The process of transforming the rainfed area must be engendered through the promotion of sustainable women SHGs. Their access to entitlement such as land, water, food for work programme and overall employment should be proactively promoted. Given the high risk, coupled with the low investment capacity of the farmers and other inhabitants of rainfed areas and the acute distresses created due to layers of indebtedness through borrowing from non-formal institutions, highest priority should be given to the access to formal credit, insurance and other institutional supports particularly to the weaker sections of the society. In order to build the human capital, nutritional security of children and women through the whole life cycle approach coupled with safety net provisions should be given top priority in the hot spots. Safety nets and input supports such as development of seed villages and establishment of seed/grain/fodder banks through the leadership of SHGs and involvement of agri-clinics will prove extremely effective in enhancing food security. The Governments should proactively support the purchase of local grains, such as millets, jowar, ragi, oilseeds and pulses for stocking the grain banks. This will empower the local people both economically and nutritionally and many of these grains are much more nutritive than rice and wheat – the commodities which presently constitute the bulk of the national food buffer stock.

15. **Strengthening Enabling Mechanisms:** Livelihood of small and resource-poor farmers are directly linked with the magnitude of their marketable surpluses and remunerative returns of their products. While through group actions (cooperatives, SHGs, farmers’ associations, etc.), economies of scale should be realized by effecting the integration of production, processing, value addition and marketing, appropriate regulatory mechanisms should be in place for protecting the rights of rainfed farmers on indigenous agricultural biodiversity, which they have conserved and evolved over generations. These resources possess extremely valuable genes and constellation of characters, such as the extremely high fat content of milk of local buffalo breeds.

16. **Effective Sanitary and Phytosanitary measures and quarantine management must be in place to protect the trade and biosecurity of rainfed people (Refer Chapter VII).** In this context, necessary institutional and awareness development programmes need to be designed particularly
for the rural people, to enhance their trade, legal quality and genetic literacy to empower them for their active participation in the development process and for capturing the new opportunities.

**B. Catalytic Interventions:**

**B1 Adopting Existing Technologies:**

17. **Narrowing yield gaps:** For the last many years, the average yields in rainfed areas have been hovering around 1 ton/hectare. However, the recent on-station and operational research on large number of farmers fields across the country clearly showed that the yield level can be at least doubled to 2 tonnes/ha. if only a “campaign mode” approach is adopted to popularize the technologies matched with appropriate policy and institutional support. Some of the key elements for the successful adoption of improved technologies are: (i) consortium approach for technical coordination and implementation, (ii) direct fund flow to the PRIs/PIAs, (iii) involvement of financial and marketing agencies at the village/district level, (iv) proper synergy with the existing schemes of the State departments of agriculture and leveraging their strengths particularly in input supply like seeds, micro nutrients, machinery and (vi) participatory involvement of the stakeholders including the PRIs, SHGs and other grass root organizations on the choice of interventions and resorting to a bottom-up priority setting based on the local needs assessed through participatory rural appraisal.

18. **Bridging the R&D disconnect:** Indian researchers, sometimes in collaboration with CGIAR and other international and developed countries’ research and technology development institutions have developed some world class research outcomes and technologies, which have substantially contributed to our agricultural production and natural resource management. These “bright” spots should be expanded and shared through traveling seminars, visits and exchange of farmers and technology transfer agents. The critical elements of success should be identified and effectively internalized in the development process. **Farmers Field Schools**, promoting farmer-farmer lateral learning, involving even the *Krishi Pandits*, should be promoted and further expanded.
19. To have a measurable impact on production, income and livelihoods at the district level, it is important that a sizeable number of the farmers in the target areas adopt technology and the institutional consortia should facilitate this through a well defined institutional and policy framework. CRIDA and ICRISAT are willing to provide this framework on a pilot basis in few districts which need to be replicated all over the country, particularly the 150 districts by involving the institutions in the National Agriculture Research System (NARS), NABARD and the private sector. For internalizing the proven technologies in the development process, Agricultural Technology Management Agency (ATMA) should strengthen its linkage with the ICAR. Private sector participation is particularly relevant in areas like input supply, soil testing and marketing. Some examples of the rainfed farming technologies that can be popularized in the backward districts are: (i) Soil test based micronutrient application for maximizing yields, (ii) Popularisation of hybrid pigeonpea, (iii) Ridge and furrow method of cotton cultivation, (iv) Popularization of high quality *arboreum* cottons (MDL-2463. PA-255 and DLSA-17), (v) Upland rice + pigeonpea intercropping system (5:2), (vi) Double cropping in rice fallows of eastern India, (vii) On-farm water harvesting in rainfed rice through dabris and (viii) Integrated rice-fish-duck farming system. Nearly 2000 large-scale farmers’ fields demonstrations are proposed.

20. Other promising technologies which have equal potential but need some more refining are: (i) Popularization of multicrop safflower harvester, (ii) Multipurpose 6 row seed drill for rainfed crops, (iii) Water harvesting through small farm ponds, (iv) Improved intercropping systems for different agro ecological regions of the rainfed crops, (v) Ridge and furrow planting method of rice + pigeon pea, (vi) Popularization of improved rabi sorghum variety CSV-216-R, (vii) Utilization of sunflower heads as a cattle feed through pulverizing machines, (viii) Pulse beetle control in stored pulses like redgram, greengram and blackgram through probe cum pitfall trapping, (ix) Improved storage of soybean seed for increased viability (vacuum storage techniques), (x) Horti-agricultural system in rainfed areas and (xi) Improved livestock nutrition. For these, 3,000 demonstrations are proposed. Micro enterprises for landless workers needing widespread adoption are: (i) Promotion of using improved machinery through custom hiring centres (for seeding/tillage/interculture/harvesting/threshing/shelling and drying), (ii) Kisan nurseries for landless women, and (iii) Village seed banks: about 1500 seed banks (10 villages in each of the 150 districts) may be set up.
B-2 Transferring New Technologies:

21. The following thematic interventions are considered the most critical towards increasing productivity and livelihoods in rainfed areas: (i) water resource development, (ii) investing in soil health, (iii) integrated crop management and production, (iv) integration of alternate land use with livestock/aquaculture/horticulture, (v) post harvest management, processing and value addition, (vi) micro-enterprises and marketing and (vii) social engineering, group dynamics, engendering the movement; expanding the knowledge base.

22. Based on the research done and the successful cases of transfer of some of the technology packages in selected pockets in different zones of the country, the following interventions have been found to be extremely effective for enhancing productivity and livelihood in rainfed areas and deserve large scale adoption.

22.1 Participatory augmentation and management of surface and groundwater.
22.2 Soil test based integrated nutrient management with focus on micro nutrients and soil carbon.
22.3 Participatory selection of crop varieties and village based seed/fodder/grain banks, based on the NERICA model (New Rices for Africa adopted successfully in west Africa).
22.4 Promoting increased fodder production and livestock health care.
22.5 Production and distribution of quality planting material of horticultural crops.
22.6 Skill enhancement of artisans and promoting micro enterprises for value addition through post harvest processing and ICT –mediated knowledge sharing.

23. Soil test based micro-nutrient amendments for increasing yields: While scaling-up, the consortium model noted that with 80-100% of the tested farmers’ fields in Andhra Pradesh, Madhya Pradesh, Rajasthan and Gujarat in 200 watersheds were severely deficient in boron, zinc and sulphur in addition to the macro-nutrients like nitrogen and phosphorus. Farmer participatory trials with micro-nutrient amendments in 200 watersheds during the last 2 years increased crop yields by 30 to 120% in case of maize, groundnut, sorghum, pigeonpea, chickpea,
soybean, greengram etc. The economic gains with the application of micro-nutrients in three districts of Andhra Pradesh is ranging from Rs.1,500 to Rs.16,500 per hectare. This technology should be adopted on large scale throughout rainfed areas of the country with due attention to the 150 districts for improving the productivity of the rainfed systems. Additional facilities for soil test analysis for all the 16 macro and micronutrients are needed to implement this programme. To begin with, each district must have one adequately equipped soil testing laboratory which could reliably test for the various nutrients, especially the micronutrients. Additional investment both in terms of equipment and human resources are required to create a national grid of advanced soil testing laboratories (ref. Chapter I).

24. **Enhanced soil health through vermicompost and *in-situ* generation of organic matter:** Indian soils are severely deficient in soil organic matter which is the main driving force for agricultural production. At the same time, there are large quantities of farm residues available in the villages and wastes in the cities which can be converted into value added compost through vermi-composting. The farm boundary bunds are successfully used for generating N-rich organic matter by growing nitrogen-fixing shrubs on the farm boundaries. These shrubs can provide 25 to 30 kg of N per hectare through loppings and also improve the soil health through building the soil carbon. Both these technologies can result in building assets in the villages which will enhance the agricultural productivity and at the same time create long-term employment in the villages while improving the soil health and improving the productivity. **Small Holders’ Estates**, landless labour and non-agricultural groups must all actively promote this green technology.

25. **Availability of high quality improved variety seeds through village-based seed banks:** Timely availability of good quality seeds of high-yielding improved varieties of crops is one of the major constraints farmers face in the rainfed areas. The consortium model has demonstrated that with the support from the consortium to the farmers for producing high quality seeds using the breeders seed material, grading, storage and distribution could result in increased productivity and employment opportunities in the village. The SHGs managed the village-based seed banks and through value addition more income was generated in the village and at the same time, productivity of large rainfed areas were substantially increased. Successful examples of
village-based seed banks in Madhya Pradesh and Rajasthan supported by Sir Dorabji Tata Trust project and in Andhra Pradesh supported by APRLP-DFID projects have been in operation for the last 2 to 3 years. The villagers are empowered and are managing the village-based seed banks effectively for crops such as groundnut, chickpea, sorghum and soybean. Other governments, private sector, NGOs and SHGs should also adopt this programme.

26. **Rainwater harvesting through farm ponds for supplemental irrigation and recharging the dead open wells:** In most of the rainfed areas, the seasonal rainfall which comes as downpour, substantial part of that goes waste through runoff causing soil erosion as well as impoverishing the soil through soil erosion. It has been demonstrated throughout India that harvesting of excess runoff and storage into farm ponds as well as restoring water bodies and recharging the dead open wells is a very feasible and successful option for improving the groundwater recharge as well as enhancing the productivity of rainfed agriculture through supplemental irrigation. In the areas with rainfall above 400 mm these technologies could be widely adopted which will enhance the cropping intensity, diversify the system into high value crops, increase the productivity and incomes from rainfed agriculture and at the same time, create assets in the villages. These technologies have shown remarkable increase in the groundwater as well as productivity and incomes for the farmers. The watershed programmes should adopt a **million well recharge programme** to be linked to a rebate in the rate of interest provided under the enhanced agricultural credit programme, on priority basis. All the Technology Missions should also contribute to the national scheme to retain, renovate and restore the water bodies that are linked to agriculture.

27. **Popularization of improved high yield varieties/hybrids:** Large number of high yielding varieties/hybrids of number of rainfed crops are released by research organizations and private entrepreneurs in the country. However, availability of these seeds to the farmers is lacking in remote areas. By popularizing these improved varieties and establishing linkages with private entrepreneurs, the benefits of increased productivity can be harnessed. This technology can be widely adopted by conducting front line demonstrations on the farmers’ fields through farmer participatory approach. At the same time, linking villagers with the private entrepreneurs will increase the employment opportunities in the villages and serve the purpose of increasing
productivity and incomes of rainfed agriculture. NABARD Agriclinics, contract farming and Small Holder Estates, with active involvement of corporate sector should be the main drivers of this technology.

28. **In-situ moisture conservation through land farm treatments:** Based on the type of soil and rainfall different land forms such as ridges and furrows, broad bed and furrows (BBF), raised beds and sunken furrows, contour planting and bunding and conservation furrows at specified intervals can substantially enhance the infiltration of rainfall resulting in increased soil moisture for growing the rainfed crops. These technologies are well proven and can be widely adopted in the specific areas based on the type of soil and rainfall in the region. Through these interventions, rainwater use efficiency can substantially lower the runoff, soil loss can be decreased and productivity of rainfed systems and incomes from rainfed agriculture can be substantially increased.

29. **Integrated livestock and horticulture with crops:** Livestock are important source of livelihood for the rainfed farmers and landless people. In order to improve the livelihoods of landless people in the watersheds, enhancing the incomes through improved animal production (for milk, meat and other products), the intervention will be through improved forage production, seed quality improvement, improved animal health and breed improvement. At the same time, agricultural systems with improved water availability can be diversified using high value crops (fruits and vegetables), the incomes of the small holders can be substantially enhanced. It is proposed to target weaker sections and landless people for the livestock and small holders with irrigation facilities for diversification with high value crops.

30. **Post harvest management, processing and marketing:** Recognising that huge post harvest losses especially in horticultural and livestock and dairy products, cause significant depression in productivity, quality and income, highest emphasis should be placed on investment in infrastructure for post harvest management, transportation of agricultural goods (the production centres are generally placed distantly from the processing and marketing centers in rainfed areas), agri export zones, processing and modernized retail outlets, Growers’ cooperatives and SGHs should play an active role. The highly successful NDDB model of
linking production – processing – value addition – marketing of milk and dairy products should be replicated for other commodities. Appropriate harvesting and processing machines, shellers, threshers, dal mills, oil expellers etc. should be promoted and supported both by the public and private sectors. The involvement of women SHGs closely linked with the home science activities promoted by the agricultural universities and ICAR Institutes should be duly supported. Low cost storage structures for fresh fruits and vegetables, pulses, grain banks and hand tools to reduce drudgery among women should be actively promoted. A post-harvest technology wing may be added to the existing Krishi Vigyan Kendras (KVKs), in order to bridge the huge gap between production and post-harvest technologies, particularly in horticulture resulting in considerable post-harvest losses as well as loss in opportunities for value addition. As such, Krishi Vigyan Kendras may suitably be redesignated as Krishi and Udyog Vigyan Kendras (KUVKs).

31. The following micro enterprises and marketing approaches are strongly recommended to be adopted towards the goal of enhanced productivity and livelihood security, especially by landless and non-agricultural people:

31.1 Intensification and spread of household income generating activities like mushroom cultivation, sericulture, backyard poultry, apiculture, vermicomposting and pisciculture.

31.2. Promotion of custom hiring of farm machinery, irrigation and plant protection equipment etc.

31.3. Establishing and fostering linkages with market committees by e-networking

31.4. Linking SHGs and other farmers organizations/groups with credit, insurance, private & corporate sector to promote Small Holder Estates to benefit from the power of scale.

31.5. Establishing ICT based knowledge centre/internet kiosks for market information and virtual extension service (Refer Chapter VIII).

C. Leveraging Group Dynamics:
32. In order to take advantage of the scale of economies, small and resource poor farmers should be helped to organize themselves as **Small Holders’ Groups**, on the lines of SHGs, each covering an area of about 500 ha. About 6000 such groups could be created in the 150 districts identified by the Planning Commission. Through appropriate skill development and based on agro-ecological capacity, and strategic locations, such groups may further form themselves into clusters of groups to undertake mass production by masses of specified commodities. The smaller groups may concentrate on seeds, planting materials, biofertilizers, marketing and e-commerce. These groups should be duly empowered to enhance their access to modern technologies, formal credit and marketing. The group action will dispel the risk aversion attitude of otherwise individual resource poor farmers and other workers and will provide the necessary confidence to adopt new technologies, investments and avenues of employment and income generations. Since their access to appropriate insurance packages and life saving supports from the Government will enhance considerably, the adoption rate of new technologies and intensification processes will grow fast. Further the group action will insulate the small farmers from the gambles both in monsoon and the market place by scaling up their power both in production and distribution. The proposed **National Commission for Sustainable Livelihood in Dry Farming Areas**, through the watershed management programmes, should make special efforts to create such groups throughout the country. The role of Panchayat Raj in creation and management of such groups can hardly be over emphasized and PRIs should suitably be strengthened by providing necessary financial and human resources support.

**D. Socio-economically and Agro-ecologically Differentiated Approach:**

33. In rainfed areas, natural resources endowment and development potential vary greatly from location to location. Therefore, location specificity must be emphasized in micro planning, in allocation of resources and in setting socio-economic targets. Area-based development duly internalized in the integrated watershed management approach, should be the hall mark of development and growth of rainfed areas (Fig.1). Therefore, we propose that the agro ecological sub-regions of the 150 districts should be delineated and the various programmes should be designed to match their capacities, as illustrated in Fig.2. This will particularly be important for creating assets to ensure sustainability of the watersheds.
E. Capacity Building and Knowledge Sharing for Improved Livelihood Security in Rainfed Areas:

34. The new approach to productivity improvement and employment generation in the rainfed areas is more information and knowledge-intensive. The majority of the individuals covered require support to meet a range of information needs that arise with the deployment of new technologies and services. There is also a need to build and strengthen new local capacities in aspects of resource management and in responding to credit or market movements. Both these dimensions require a functional and affordable arrangement that brings knowledge and information sources and the rural families together for improved livelihood security of the families. Capacity building and knowledge sharing approach that integrates the bottom-up with the top-down approach is also needed.

35. Through a system of ICT based rural knowledge centres (Refer Chapter VIII), the families in the dryland areas can access information and knowledge resources with facilitation by a district-level consortium, and can raise their queries. The following figure describes this arrangement, which is itself derived from the significant national experience in rural IT kiosks in recent times.
Focus on *in situ* moisture conservation, intercropping, livestock

Land use diversification and rainwater harvesting, livestock

Scope for intensification of double cropping, rainwater harvesting

Immense scope for rainwater harvesting, horticulture

Intensification of upland rice, paddy-fish-pig integrated farming, oilseeds and pulses
Financial Resources

36. A National Network of Advanced Soil Testing Laboratories will be required towards addressing the soil fertility imbalances, particularly the deficiencies of micronutrients in the soil. Factor oriented (eg. micro-nutrient deficiencies, implements etc.) and system oriented (eg. crop-livestock-fish integration) demonstrations need to be organized in resource poor farmers’ fields by the R&D Consortium to be set up by the Commission on Sustainable Livelihood in Dry Farming Areas. Farm Schools will have to be established using the services of outstanding farmers. Additional financial resources will be required also for strengthening processing and post-harvest management, rainwater harvesting and restoring water bodies as well as for the creation of pulses and oilseeds villages. ICAR should provide part of the funds needed through re-ordering of priorities and redeployment of personnel. **An additional sum of Rs.1,050 crore, as detailed below, may be provided in the budget for 2005-06 to cater to the above mentioned requirements.**

36.1 **A National Network of Advanced Soil Testing Laboratories** – 1,000 laboratories across the country, with 500 of them located in dry farming areas, each laboratory costing Rs. 50 lakhs - total allocation Rs. 500 crore.

36.2 Five thousand large-scale demonstrations on catalytic interventions in collaboration with CRIDA and ICRISAT, establishment of 1,500 seed banks and creation of 6,000 Small Holders’ Estates - Rs. 100 crore.

36.3 Establishing 50,000 **Farm Schools** in the fields of framer-achievers - Rs. 150 crore.

36.4 Post harvest processing and value addition in collaboration with CFTRI and private sector and strengthening of **Krishi and Udyog Vigyan Kendras** for post harvest management - Rs. 150 crore.

36.5 Augmenting water availability by vigorously promoting water harvesting and restoring water bodies – Rs. 70 crore.

36.6 **A Million Wells Recharge Programme** ( to be promoted through interest rebate on loans)
36.7 Rainbow Revolution in rainfed areas achieving substantial enhancement in productivity of millets, pulses, oilseeds and livestock through large scale adoption of highly successful new technology packages, such as hybrid *arhar* - Rs. 50 crore.

36.8 Creation of pulses and oilseeds villages (*Arhar Villages, Sesamum Villages*) for specialized enhanced production, efficient processing and remunerative producer-oriented marketing of the selected crops - Rs. 30 crore.
CHAPTER IV
A NEW DEAL FOR WOMEN IN AGRICULTURE

The Sixth Five-Year Plan (1980-95) should be remembered as a watershed in the history of post-independence Indian planning. For the first time, the Plan document presented a separate chapter titled Women in Development. Government of India had finally accepted that women were vital actors, contributors and agents of development planning. Since then, each Five Year plan introduced development schemes for women. An illustrative list of the important and significant programmes presently being implemented in the Ministry of Agriculture (MOA) is provided below:

- The Central Sector Scheme of Women in Agriculture (launched in the Eighth Plan) (now covers 15 States in the country)

- Externally aided projects on Women in Agriculture: (the earliest of these began in 1982, now running in 4 States)

- Externally aided GOI-UNDP Food Security Programme (began in 1998, running in 4 States)

- Projects to promote women’s involvement in the cooperative movement (as part of the general education programmes of the National Cooperative Union of India; formation of self-help groups of women is one of the activities)

- Gender-friendly agricultural Implements and Machinery: (as part of the MOA general programmes on implements and machinery)

- General programmes of Integrated Pest Management, National Perspective Development Plan, etc. also specifically focus on women in training programmes, access to subsidized equipment and earmarking of benefits at the field level.
• Organic Farming: A National Project on Organic Farming has been formulated in the Tenth Plan, and a National Institute of Organic Farming has been set up as a Central body. The links between women, biodiversity and organic farming make it one of the potential programme areas for women farmers.

• The MOA has mandated 30% of benefits from all development programmes to reach women, the target date for which is proposed by MOA as 2006-07.

2. These programmes are a mix of a) those specially designed for women, b) those that form components or have special focus on women as part of larger programmes, c) those that bear critical importance and potential for women.

**The Path Ahead:**

3. The Common Minimum Programme (CMP) provides that -

“The UPA government should ensure that at least one-third of all funds flowing into panchayats should be earmarked for programmes for the development of women and children. Village women and their associations should be encouraged to assume responsibility for all development schemes relating to drinking water, sanitation, primary education, health and nutrition.”

“Complete legal equality for women in all spheres should be made a practical reality, especially by removing discriminatory legislation and by enacting new legislation that gives women, for instance, equal rights of ownership of assets like houses and land.”

4. In the current context of the increasing feminization of agriculture, planning for women in this sector needs to keep their critical role in view in –

1. Conservation
2. Cultivation
3. Consumption
4. Commerce
5. Keeping in view the above perspective, a three-pronged approach for engendering the Tenth Plan for Agriculture is required:

- New special programmes for women with specific focus on the most marginalized families of the farming and rural labouring population and their gendered situational needs

- Affirmative action for women farmers in the programmes being currently implemented by providing 30% of benefits (including selection of numbers of women in participation in programmes as well as programme benefits) with specific reference to training, extension, provision of inputs, subsidies and support services etc. with effect from 1/4/05.

- Creation of institutional mechanisms for a) integrating women farmers’ concerns in ‘mainstream’ agriculture at policy, strategy and programme levels and, b) incorporating gender analysis, gender-sensitive monitoring and evaluation and stronger affirmative action for women

6. Agriculture for the purpose of this Chapter, from the women’s context, is envisaged in the broadest dimension. It is not restricted to cultivation only. It includes not only crop production and horticulture, but also dairying, small animal husbandry, fisheries, poultry, natural resource management in its widest sense (including forestry, tree crops, minor forest produce) as well as subsistence production. It requires creative and combined approach in order that women workers belonging to small and marginal farmer households can use a small piece of land optimally to generate year round employment. It calls for promoting a farming systems approach based on crop-livestock-fish integration, but goes even further.

7. Given this comprehensive operational framework, the suggestions made in this chapter cut across conventional sectoral lines of subject-matter demarcation; inter-sectoral collaboration and coordination is therefore of prime importance to the success of these ventures. The
mechanisms that are needed for ensuring such collaboration and coordination have, however, not been gone into in detail in the chapter.

8. **New Programme Initiatives:**

8.1 **Rights, entitlements and better access to land, water and other physical resource base:**

8.1.1. Effective access to land is perhaps the single most significant determinant of economic and social status and power in rural India and “women’s unequal access to it is one of the most important forms of persistent gender inequalities in India today” (Bina Agarwal, 2004) (mimeo). Land is a productive resource and placed in women’s hands means well-being of the family, as evidenced in better access to education, health and nutrition of its members, especially the children. In the interest of social justice as well as well-being of families, enhancement of women’s rights and entitlements to land deserves to be the first priority on the agricultural agenda. “In other words, enhancing women’s direct access to land in the rural economy could prove critical for meeting the national goals of improving food and livelihood security, children’s welfare, agricultural productivity and women’s empowerment”. (Bina Agarwal 2004)(ibid).

8.1.2 Women have been agitating for better access to credit and credit instruments. It is the absence of land titles that prevents women farmers from being granted kisan credit cards.

8.1.3 For the purpose of this section of the chapter, accelerated programme activities based on the following are recommended to be taken up –
i. Existing policy pronouncements and directives of direct transfer of government land to women,

ii. Improving inheritance rights of women to land by bringing changes in laws and working towards better implementation,

iii. Enabling women to buy land from the market

a) Transfer of Government land, including wasteland, ceiling surplus land, etc. to women

Government has issued policy directives from time to time to all States on allotment of land on joint pattas in the names of husband and wife. In addition, Government has also issued directives on allotment of such land in the names of women only. The Sixth Plan recommended allotment of at least 40% of land pattas to women and the remaining pattas in joint names of husband and wife. This was further taken up in the Seventh Plan as well as in the National Perspective Plan for Women (1988-2000). Allotment of land under various welfare and anti-poverty schemes on the basis of joint pattas to husband and wife is a part of Government policy of strengthening women’s legal entitlements.

Since the subject of land is within the competence of the State governments, the implementation of these directives is not uniform. Nor is there an effective monitoring system in place at either State or central level. While some States have gone far ahead and have issued orders for enforcing land transfers to women or in the joint names of husband and wife, some others have not been proactive.

Joint pattas give a measure of protection to wives against indiscriminate sale by husbands without consulting them. In case of marriages breaking up, joint pattas ensure a share in the property to the wives. However, joint pattas have several flaws, as women are not able to have legal rights of disposal of the land. Women also find it difficult to access the produce of the land and enjoy it. Joint pattas also
obstruct women from joining with other women to take up agricultural activities as a group.

The Center of Rural Studies, Lal Bahadur Shastri National Academy of Administration, Mussoorie has brought out a number of publications on gender discrimination in land ownership. These studies bring out that the majority of women, especially those who belong to the target group of welfare and anti-poverty programmes, under which these allotments are made, are themselves not aware of these Government directives and of their entitlements to land. In the Uttar Pradesh study, (covering two districts), none of the rural households interviewed reported the case of any such land allotment, either on individual or joint patta basis under the land reform programme. They did not understand the phrase “joint patta” and expressed their ignorance of the government directives on land allotment. In Orissa, the study found that land compensation for development projects was paid to the male heads of families only. In case of landowners who were female-heads of households, widows, or destitute women, etc. the compensation was diverted to middlemen or others who cheated the women of the money. Government of Orissa had issued its first directive on grant of joint land pattas to husband and wife in 1989. In October 2002, the Government further directed that 40% of the Government wasteland allotted for agriculture, ceiling land, bhoadan land etc. may be allotted to widows, unmarried women, victimized women and women living under the poverty line as far as is practicable. No consolidated information was made available to the research team on the progress of implementation of these directives. There was some evidence of title transfers
on joint patta basis in a few places where the administration had started the same on “experimental basis”.

Programme activities for 2005-06 should focus on –

i) Setting targets State-wise, for allotting at least 40% of government land distributed (including water bodies, wasteland, surplus land, etc.) to women’s groups for taking up agriculture and allied activities.

ii) Setting targets State-wise, for allotment of remaining government land transfers on the basis of joint pattas to husband and wife

iii) Setting targets State-wise for at least 40% of government land distributed to SC/ST to go to the women of these communities.

iv) Allocation of land in State Farms (both Central and State) to women SHGs engaged in the production of seeds and planting material for horticultural crops including medicinal plants.

Though ‘land’ is a State subject, the Central Government should oversee this programme and monitor its implementation. Most of these directives on providing titles to land for women emanated from Central Plans, based on the recommendations of planning groups and other high level policy making bodies.

The Central Government and State Governments can earmark land on government-owned farms to be given to Self Help Groups (SHGs) of women for agricultural purposes.

Monitoring of the implementation of grant land titles on exclusive or joint patta basis to women should be taken up as a new programme and should form a part of
the Ministry’s activities during 2005-06. Such a pro-active step by the MOA should establish that programmes and policies for women in agriculture cannot be designed and carried out without reference to legal rights as well as access to land. It is not enough to provide women with access to knowledge, skills and productive resources such as credit and technology, marketing, quality control, etc. without legal entitlements. It is necessary for MOA and its various agencies to be seen as supporting affirmative action to raise women farmers’ status by facilitating their ownership and access to land and other physical assets.

MOA should carry out 4 regional consultations on issues of land rights and women during the FY 2005-2006 in collaboration with State departments of agriculture and rural development (among others). In addition, a special consultation should be held in the North-East region where issues of land rights and women need special attention.

b) **Private land**

In the short term, overcoming existing legal obstacles to equal access to land and property for women pose grave challenges. However, the need to provide equal rights to land through amendments to existing laws cannot be put on the backburner. Follow up of earlier initiatives should be accorded top priority. Union Cabinet has recently approved amendments to the Hindu Succession Act 1956, providing that daughters would get equal rights in ancestral property.

While ownership of private land is skewed by both class and gender in India, it is ironical that the largest numbers of women farmers and workers in agriculture belong to the tenant category, who work on the lands belonging to others. Share cropping and other similar systems provide livelihoods to the largest numbers of families in the country and in the background of increasing male out-migration, women have become effective share croppers in large parts of the country. Though it is a loss making activity, it generates foodgrains and provides a modicum of food security. These women have no better
alternatives and stand marginalized by banking institutions, agricultural and scientific establishments and governments. With increasing feminization of agriculture, these women are taking up more and more of agricultural tasks hitherto carried out by males. They have no security of tenure and are seldom allowed to cultivate the same piece of land continuously. They have no access to credit and therefore buy the agricultural inputs, often of poor quality, at exorbitant prices, some safety nets are required for this very large category of women workers, for which NABARD can set up a working group or a committee.

c) **Purchase of land from the market**

There is also the successful initiative where a Scheduled Caste Development Corporation (SCDC) (Andhra Pradesh) has enabled dalit women’s groups (by giving subsidized credit) to purchase/lease private land from the market for cultivation of crops. The ownership rests with the group, which manages and controls the land and its cultivation. The SCDC has sought partnership in this endeavor from NGO’s working in the State. This initiative can be recommended to the other States, especially where the problems of landless dalit women are in large numbers, either as an alternative or in conjunction with the grant of leases/pattas of government-owned land.

### 8.2 Improvement of land records to strengthen women’s land security

*Special problems arising from lack of proof of community-owned land: the case of the North East*

Women in certain areas or belonging to certain communities of the country, especially the North-Eastern region, are often handicapped in the absence of legal proof of entitlements to their customary and traditional rights to agricultural lands as well as the accompanying responsibilities that they are required to carry out. The All India Federation of Women in Agriculture has demanded a cadastral survey to be conducted in the North Eastern region, which should enable the women as well as the men to have proof of the ownership of land. Though land is
not a problem in this area traditionally, as it was considered ‘non-tribal’ not to own land, with increase in land grabbing, problems are arising. The privatization of community land is increasing and land is being leased to private groups.

The North East region is known for its customary land systems adhering to tribal and other ethnic norms of property ownership and use in which the community ownership is predominant. However, in most areas of this region, the land system has not been codified nor cadastral surveys conducted. This has led to a situation where there is no record of land rights. With the increasing socio-economic changes and trends towards modernization, community and communally owned land resources are in danger of being encroached upon by individuals. Pattas are being issued indiscriminately by local authorities that do not have the sanction of customary laws. Women stand to lose a great deal in these transactions that are taking place. Their control over natural resources is getting more and more endangered with the conversion of community-owned lands to private property. The conventional images of women of the north east region having property rights is not always borne out by actual field realities. Even if women have proprietary rights over land, it is the males who may more often control its use. The decline of jhum cultivation and its replacement by conventional individual farming is an example.

The urgent necessity of undertaking a comprehensive survey of the land and preparation of a statute book or a compilation of record of rights based on cadastral maps has been emphasized by many authorities, including some of the high courts and land reforms commissions in the region. Even when some of the States have passed enabling legislation to provide for surveys, the same have not so far been enforced for all the States of the region as a whole.

A comprehensive survey of land ownership in the North East should be taken up during 2005-06, using the latest technology so as to ensure accuracy of mapping as well as saving of time. Ensuring a participatory and transparent process to the
planning as well as the conduct of the survey is vital to its success. Unrecorded rights traditionally enjoyed by individuals or groups, such as women (but not confined to women only) run the risk of being excluded when a formal exercise of surveying ownership rights and then recording them, collects oral evidence and uses it as an important input. Very often members of marginal groups fail to turn up for the hearings. It is essential that all women of the region and the areas being surveyed are consciously involved in the process. In order to give wide publicity to the process, public hearings can be made an integral part of the process. Disputes and jurisdictional complexities can be dealt with better by using such open forums.

Clear village-scale maps, using informal and formal mapping methods including GIS and GPS, and a database of the updated land records should be prepared. Records of land rights can be computerized and made available in hard copies to local agencies for public use and perusal. Capacity of local women and men to upgrade the records from time to time should be built.

Apart from the special issues relating to land records of the North East region, there are other problem areas in the rest of the country that obstruct the enjoyment of women’s rights over land in the possession of the family.

8.1.4 There are two other problem areas needing interventions at various levels –

a) Absence of women’s names in general in the land records of land-owning families: Generally, only men’s names are shown as owners of land. Women’s names are often not recorded as claimants. This is more so in the case of daughters. Improving the maintenance of land records is in the interest of increasing women’s ability to obtain land from their families and ensuring that their claims are properly recorded in the village registers. Women’s names go by default in the ownership or possession columns. Since 86% of arable land is privately owned, the absence of revenue record showing women’s claims to
land severely affects women’s capacity to take up productive land-based activities on ownership basis. The example set by the Government of Assam is worth emulating. In 1989, it took a policy decision to include the name of the wife in settlement pattas. It was part of the Government Land Policy of 1989, which marked a complete departure from the earlier State land policies, which did not mention women by name. The Policy stipulates that all allotments and settlements of land, both in rural and town areas, should be in the names of the spouse, conferring joint title to the husband and wife of a family. The State Government followed this up by issuing patta passbook with specific columns to show shareholders of the property. Even though the policy of inclusion of wife’s name in the settlement pattas has remained on paper in the State, the initiative taken by the State to include this provision in the Land Policy is worthy of emulation by other States. It protects the inheritance rights of women, especially of widows. This can be recommended to other States in the country. On the analogy of the Assam initiative, MOA should ask all State governments to include the names of women family members in the revenue records as claimants of landed property.

b) **Problems arising from lack of recorded rights of certain exclusive communities:** Rights of women of the traditional farming communities, pastoral, artisan and fishing communities, women’s share of common property rights over pastures, forests, wetlands, and other lands are seldom recorded. The same situation exists for individual rights of women and men over agricultural fields. Most nomadic communities have no written record of the rights enjoyed by them. They exist in a State of uncertainty, because they do not have a title deed to the lands and waters that they have traditionally or customarily used for their livelihoods. This situation often creates indifference and a lack of stake in maintaining and enhancing biologically diverse, sustainable farming, pastoral, and fishing practices.
Improvement of the preparation and maintenance of land records is to ensure women secure and clear tenure, especially women of communities who traditionally enjoyed common property rights in the absence of any record or document of these rights. Women holding individual rights over agricultural land are also benefited by the proper upkeep of land records.

A similar exercise should be carried out for customary/traditional right-holders such as tribals, nomadic groups, pastoral communities, traditional farmers, artisans, fishing communities, etc. with special focus on women in these communities. What is needed is to compile and collate existing records at village level, so that it is possible to look at issues of conflict, areas of dispute and at competing claims and try to arrive at solutions amongst the different parties involved including the government departments. Women of these communities should be involved in these village level discussions and public hearings.

A large number of line agencies should be involved in these exercises. The objective should be to move towards a secure and clear tenure by way of both individual and common property rights that can be recorded and made into a document that is easily accessible to every one at the village level.

8.3 Partnership programmes in promoting women’s productivity (Supporting women’s groups in enhancing productivity with the help of established women’s organizations working at grassroots level)

8.3.1 In the short and medium term, poor women’s groups should be provided programme support (technical, financial, management, etc.) for agriculture, horticulture, fisheries, wasteland development, rejuvenation of grasslands, natural resource management, village pond development etc. through the agriculture and allied extension machinery backed by NGO support. Instead of following the
conventional top-down approach whereby government ‘motivates’ the ‘beneficiaries’ to avail of new government schemes and projects, the MOA should make efforts to identify groups of women where a latent demand for such opportunities already exists (the term “beneficiary” denotes a patronage approach; there is need for a shift in mindset from patronage to partnership).

8.3.2 Those grassroot organizations in different parts of the country who have successfully spearheaded poor women’s groups to demand land from the government should be involved by the MOA in these efforts. Organizations that have achieved many successes in these fields should receive formal recognition as resource agencies to help the MOA for designing and running these programmes, according to the needs of the local context and situation.

8.3.3 Organizing and mobilizing poor women who are in search for new alternative livelihoods is an essential ingredient for the success of these programmes at the local level. This enables women to create their own organizations, whether in the form of self-help groups, cooperatives, societies or other forms. It is only as members of their own organizations that the women can aim to increase productivity, income and bargaining power. Such a partnership should enable MOA to avoid the pitfalls of a ‘targeted’ approach where quantitative aspects are deemed to be a measure of success.

8.3.4 The group approach is essential to strengthen women’s capacity to retain control over the land as well as to access production resources of better quality with greater ease and convenience. The entity of a group also enhances the status of women as compared to individual leases or pattas. This should be therefore a non-negotiable feature of this scheme.

8.3.5 This programme initiative should take the following elements into account:
a) The State authority enabling ownership of/access to land by hitherto landless or land-poor women organized into groups through its rules and procedures.

b) The presence of intermediary organization(s),

c) Fostering a collective ethos amongst the women through mobilization of a broadly homogenous set of asset-poor women, which is essential to the sustainability of the programme;

d) Mobilization, specifically in the context of building an organization of women workers.

e) Mobilization around issues that are local-specific, differing from area to area on the basis of agro-climatic or other factors; relating to challenges that the women have to battle with for survival and subsistence, such as water, soil, natural calamities, displacement etc.

f) Involvement of women not only in crop production but in any of a sweep of activities based on land and water, bio-diversity, natural resource management, etc. with an open-ended approach.

g) The importance given to removal of food insecurity at both the household and community levels as one of the main objectives of the programmes.

h) The asset-poor women’s collective entity cannot be restricted to the self-help group model alone (which is what most of the MOA programmes are based on) as the funding norms may not suffice. There is a need to look at other models such as the cooperative, the mahila mandals, village groups, or others. Different organizational models could be combined, as for example, a women’s cooperative at the district or sub-district level could mobilize women into self-help groups/credit and savings groups or other informal groups or sanghas at the village level. These formations of women should be legally eligible and authorized in terms of policy mandates to lease or purchase land for agriculture. Self-help groups of women, for example, should be given the
same status as farmers’ groups in accessing resources for land-based activities.

i) Self-help groups are generally understood in a narrow and instrumental sense, as a conduit for delivery of services. They should not be merely instrumental entities, or used for their instrumental value, but should be strong collectives of women. They should be sustainable SHGs, ensuring backward linkages with technology and credit and forward linkages with markets so as to generate both farm and non-farm livelihood opportunities. In order to upscale their activities (such as marketing or quality control), they could join to create federations at higher cluster levels. Management of sustainable SHGs should be improved and made more transparent by introduction of relevant accounting software.

8.3.6 Programme components should broadly cover food and nutrition security at community and household levels, conservation of bio-diversity, organic farming, information dissemination and documentation of best practices, community-based production, storage and distribution systems, popularization of traditional health foods, etc. Specifically, they should focus on the women of the poorest and most vulnerable communities (such as dalits, marginal and landless families and agricultural labour) and could include the following illustrative activities:

A. Food Security of communities and Households Agricultural Biodiversity Documentation

(a) Encouragement of alternative public distribution systems based on locally produced food items, especially organic food and coarse grains;

(b) Support women in the communities to launch and participate in movements to save and preserve several varieties of indigenous seeds of crops such as rice,
rajma, millets, vegetables, spices, herbs, etc. (on the analogy of Beej Bachao Andolan of Tehri Garhwal);

(c) Initial support in the form of wheat, rice, or jowar to local SHGs and groups to establish food, feed, fodder and water banks can be thought of. Such banks can be operated by SHGs on revolving funds basis

(d) Integration of locally produced foodgrains and food items within the State sponsored programmes such as Integrated Child Development Scheme (ICDS), Mid day Meals, etc. Gram Sabhas and village panchayats can monitor the extent of use of locally produced food grains and food items in these programmes;

(e) Creation of community grain banks and seed banks by women’s groups/NGOs for retrieving and conserving local varieties of grains, millets, pulses, oilseeds, etc. for ensuring regular supply and distribution of seeds to farmers (on return basis as well as outside sale) aimed at conservation and food security;

(f) Promotion of organic fertilizer, especially for homestead vegetable production

(g) Support to women’s groups in villages for retrieving varieties of traditional grains such as millets, pulses and oilseeds and for conserving them in community banks at the cluster level;

(h) Encouraging cultivation of bio-diverse crops and augmenting the seeds that are vanishing or are becoming scarce at the local level;

(i) Retrieval and conservation of seeds at the village level by women farmers;

(j) Encouraging women’s groups to grow organic spices under the scheme launched by the Spices Board;
(k) Support training of local women’s groups to produce compost manure and vermi-compost;

(l) Bio-diversity festivals and contests, kitchen garden contests;

(m) Documentation of women’s oral knowledge of traditional systems of cultivation, including those based on agro-biodiversity, which are still evolving in dynamic modes and innovations; methods of seed selection, preservation, storage, crop planning, conservation of germplasm, management of yield and production vis-à-vis diversity of land types; recipes, nutritional, dietary and recuperative value of traditional crops; collection of data on domesticated diversity from villages, information on livestock diversity; local knowledge and practices of women on the nutritive and medicinal qualities of both cultivated and uncultivated foods; women’s contribution to local subsistence economy and use of local natural resources, women’s experiences of seed selection and storage practices

(n) Better access to credit, technology, collaboration with technical, financial and management institutions;

(o) Promotion of legal literacy relating to Protection of Plant Varieties and Farmers’ Rights Act, 2001 as well as on Biodiversity Act, 2002; and the urgent need for making the implementation rules for these Acts gender sensitive.

B Women’s Rights to Common Property Resources and Role of Village Panchayats

The one million elected women representatives of the panchayati raj institutions can play a major role in conserving common property resources for sustainable use in the following ways:
Support to poor women’s groups dependent on village common lands for grazing their livestock by not diverting them to other uses;

Legally enabling women to manage part of the common lands by handing them over to women’s groups for meeting their needs of fuel, fodder and pasture;

Support to women’s groups to access village water bodies to promote fish farming; one third of village ponds and water bodies to be leased by panchayats to self help groups or other formations of landless and poor women for fish rearing;

Support to training in skill development and training programmes targeted at women involved in fisheries;

Panchayats to respect and pay due consideration to women’s priorities in the management of common lands; village common lands used for grazing of livestock;

Technologies for wasteland development such as agro forestry, planting of bio-fuel trees, fertilizer trees, arjun trees for tassar rearing, could be supported on leased common lands over a viable time period;

Support to programmes aimed at increasing women’s ownership of livestock by improving their skills of management and increasing their income by better marketing through cooperatives and other channels;

Support the designing of training programmes for women as para veterinarians with focus on women’s traditional knowledge of animal healthcare remedies.

The list of the possible activities to be taken up by women’s groups given above is largely based on actual grassroots initiatives and experiments. A study of these initiatives of action groups outside the government, which have recorded success reveals a process-oriented approach rather than a target-oriented one. It is suggested that MOA
launches this programme in the FY 2005-06. The ground should be prepared by holding formal but intensive discussions with the State governments and the partner organizations with the full involvement of the National Board for a New Deal for Women in Agriculture (proposed in para 8.8), which could form a sub-group for this purpose. A few projects can be initiated during 2005-06 where enabling conditions on the ground are present. The launch of the programme, however, needs the legal and procedural conditions of lease and patta to be put in place by the State Governments and adequate land (revenue, forest-degraded, common property) to be identified well in time. MOA should therefore monitor the progress of the State governments and agencies, especially in those States where food insecurity is a major problem.

8.4 Engendering the Agriculture Curriculum

Both proactive efforts and consistent follow up are needed to remove gender stereotypes and build awareness about women workers of whom, in developing countries more are concerned with land and agriculture. This is specially vital for educational institutions.

Kerala University, in collaboration with M S Swaminathan Research Foundation (MSSRF), has pioneered a course for undergraduates in agricultural colleges / universities since these students are the potential future professional leaders in areas such as research, extension work, policy, teaching and activism.

The course has the following specific objectives: -

1. To build a perspective by providing an overview of the social construction of gender and gender inequality.

2. To create skills by identifying gender roles, rights and responsibilities and their bearing on gender relations.
3. To bring about attitudinal change, creating gender sensitivity and helping students to internalize equity concerns as fundamental human rights.

The course consists of two modules, one on gender relations and rural livelihoods and the other on gender issues in different agrarian sectors. Teachers can use it as it is or adapt it to suit local-specific learning objectives in any University. It can be adopted for use with undergraduates of any discipline.

Other Agricultural Universities as well as those belonging to the Veterinary, Fisheries and Forestry disciplines should be asked to take up similar programmes. The process should be completed by 2005, the tenth anniversary of the Beijing Conference since its outcome document, the Platform for Action, has been ratified by the Government of India. In the Platform For Action, under the thematic area Women and the Economy, member-countries of the UN have pledged to promote women’s economic rights, including access to employment, appropriate working conditions and control over economic resources and to eliminate occupational segregation and all forms of employment discrimination.

8.5 Gram Panchayat Mahila Fund for Women

Under the provisions of the 73rd Constitutional amendment and the revised State Panchayat Acts, responsibility for agricultural development now lies with the panchayats. The village panchayat has one-third representation of women. Most State Acts have a provision for special committees, standing committees or sub-committees to be constituted by the village panchayats from amongst its elected members (including its women members) to look after broad categories of production, finance and social justice. These committees interact with a whole range of representatives of line departments depending on their mandated areas of jurisdiction. There are very few States that have specific policy or legal requirements that elected women panchas should be members of any of these committees. In some States, there is a requirement that a women member should be part of the Social justice committees.
The presence of one third elected women in the village panchayats or approximately one million elected women members is crucial and opens a door to possibilities of greater collaboration and coordination between them and the women farmers in the area. This is a potential that has not yet been tapped fully for the purpose of engendering of the Gram Panchayat budget. The CMP has indicated that 30% of the Gram Panchayat funds would be allocated for women’s programmes.

Part of these specially allocated funds could be used as an incentive for initiating the participatory decision making process in which the elected women representatives (EWRs) and the farmwomen could be partners.

A Gram Panchayat Mahila Fund (GPMF) should be created for this purpose. In the initial stage of this new programme, the Fund could be started in selected 10,000 Gram Panchayats in the States. The GPMF should accord priority to building technological skills, providing information and empowering women in agriculture. This fund could be used for the purpose of establishing a facility, like women’s toilets, or for purchasing an item of equipment that should serve the needs of farmwomen in their role as farmers. It should meet the common need of the women farmers and not of an individual woman farmer only. A small fee or rental can be charged from the users by the Fund managers/Gram Panchayats.

Members of Parliament are allocated financial resources for their constituencies which they can use with a great degree of flexibility for public good. GPMF should enjoy a similar flexibility for taking up community activities that help to meet essential gender specific needs.

Some illustrative examples of its use are:

Tools that can benefit women in their farm work such as seed drills, levellers, winnowers etc. or in post harvest processing work, such as dal splitters, etc. can be included.
The GPMF can establish a common facility that can be used by groups of women farmers for drying of crops, or for seed banks, nurseries, compost making, water ponds, cattle troughs, etc.

The Fund can be used to procure services from external sources to meet women farmers’ needs such as veterinary and poultry services, information on specific crops and technologies, etc.

The Fund can be used to provide training for building women farmers’ technical skills, build an information database that can be used by the women in the village and empower the women through better access to information.

To the maximum extent, the suggestions given in this chapter on starting new ventures by women’s groups could be tied up/converged with the funds from this source to be managed by the Panchayat. However, the following should be ensured:

1. The Fund should not be used for distributing money to selected beneficiaries for any agricultural or allied purpose. It should be used only for spending on common facilities.

2. Training programmes should not be covered, but equipment and sheds for training can be included.

3. The scope of ‘agriculture’ for the purpose of using the Fund would conform to the suggestions made in this paper (“integrating” approach that would enable optimal use of land, water, livestock, commons, forests and allied resources). It would not include income generation activities unconnected with the primary sector, (such as sewing machines, repair of schools, literacy, etc.). However, infrastructure and facilities for essential child support services for women farmers could be included as a special case on strategic priority depending on the context and in consultation with all partners.
4. The Fund should remain a dedicated Fund and should not become a part of the GP general fund. It should be administered under the leadership of the EWRs with the consent of the GP as a whole.

Selection of the Gram Panchayats could be attuned to the following factors:

1. Number of active EWRs in the GP
2. EWR holding the position of Pradhan or Up-Pradhan
3. An active Standing Committee on Agriculture/Production set up in the panchayat, preferably with an EWR as a member.
4. Presence of resource organizations (very widely defined) in the vicinity for technical advice, back up and hand-holding, whose interest in land-related gender issues is well-known.

5. Presence of any type of extension machinery for farm women.

The elected women could initiate a participatory decision making process with the women farmers of the panchayat belonging to small and marginal/subsistence farmer families. The farmwomen of the Gram Panchayat supported by the EWR’s of the Panchayat could take decisions on how the fund shall be used and this should then be discussed in the Gram Sabha in which the village women should take part. This should be preceded by a series of participatory and consultative dialogue amongst the elected women, the farm women and the gram panchayat on how the fund should be used.

The quantum of funds to be placed in the GPMF depend on many factors. However, it may be of the order of Rs. 2 lakhs in order to be effective and meaningful. The administration of the Fund by the Panchayat should also be overseen by the EWRs and it is essential that the Gram Panchayat, by a resolution, delegates the maximum power of administering the Fund, to the EWRs.
One of the likely and desirable outcomes of the Fund use should be an enhanced status to the Standing Committee on Production/Agriculture and the nomination of more EWR’s to it.

8.6  
Child Care as an essential Support Service to Poor and Needy Rural Working Women

Target group

The term “rural poor women” includes women small and marginal farmers, women farm labourers, including temporary and seasonal labourers, women in fisheries, forest-based activities, fuel and fodder gathering, livestock rearing, agro-based activities, and home-based work. Such women require child care services because of their “triple roles”-they are engaged in productive economic work, household chores as well as having exclusive responsibility for child care, and are often unable because of poverty, lack of time and resources to effectively attend to all three.

The age-group for which child care services are required is 0-5 +, with special emphasis on the age-group 0-2, that is, children below three. This age-group is important for the following reasons:

- Criticality of the period not only for brain growth, of which 80% is completed by the age of two, but also for overall development—physical, mental, emotional and social, and as preparation for education

- Evidence of continuing malnutrition (0-2), high infant and child mortality, maternal anaemia, and other indicators of human development.

Basic components of the services
Child care for this age-group, to be effective, that is, to combat malnutrition and provide an environment for healthy and all-round development, must include the following components:

- Food, adequate in quantity and quality. The word quality implies not only its nutritious value, but also that there is a proper combination of semi-solid and solid foods, adapted to age, hygienically prepared, and offered at frequent intervals throughout the day (about five times a day for children below eighteen months) and with attention, affection and concern).

- Reasonably safe and healthy environment, and some stimulation, attention and interaction

- The above two conditions can only be met by the continued and regular presence of an adult care provider with some skills and a warm and caring relationship with the child.

- This implies that for the youngest children the ratio of adults to children has to be high enough to allow for care, attention and interaction.

To meet these conditions, especially the first, day care is a must for large numbers of poor rural working women. Mere distribution of food supplements at a feeding center is not enough. However, child care, especially of the youngest, is a highly context and situation specific activity. For example, some women may need child care for eight to ten hours a day, others for only four or five hours, and the actual duration and timings for which it is needed may vary. Again, women working as temporary or seasonal workers may need it only for specified months. Effective day care may be one way of attacking multiple problems.

Basic principles for implementation
Experience has shown the desirability of some of the following principles of implementation

1. Plurality of models - a single monolithic model for all situations in a diverse country is not appropriate. In practice, four models may be sufficient at present.

2. Context-specificity - making services/programmes very specific to local needs and demands, locally determined.

3. Flexible norms and ratios -- ratios such as population-centre ratio and worker-child ratio should be worked out for different situations.

4. Per child per day cost norms. If diverse and flexible norms have to be adopted, then it is more practical to provide a per child per day norm as the basis for funding and leave it to the programme authorities in each case to work out the nature of the programmes and activities.

5. Decentralisation. The responsibility, as well as the funding and powers for management of child care support services for women may be handed over to local Bodies (PRIs). This would enable them to fulfil the responsibility of catering to all children, especially the most vulnerable ones, in their jurisdiction, and break the stranglehold of the norms relating to size of the “habitation” which is entitled to have a center.

Advantages of decentralisation

Local procurement of food for the programme from local sources, cutting down the wastage, delay, leakage and other problems connected with centralized storage
• Linking up centralised sources with local grain banks for food supply and promoting the grain bank movement for food security in rural areas.

• Local cooking and serving of food with the help of local women, either through SHGs or other organizations. Successful examples of SHGs supplying food to anganwadis already exist.

• Monitoring and supervision of the crèche and child care services with the help of women members of the PRIs, local grassroots organizations, womens’ groups, and where available NGOs.

• Monitoring by the women users on a day to day basis, and responsiveness to their needs.

• User fee. Experience shows that where there are quality services, women are not only prepared to leave their children there but even the poorest users are willing to pay a small user fee. Confidence in the service has to be established first.

Models

A four-model scheme of child care services (including day-care) for the 0-2 years is recommended to be launched during 2005-06 in rural areas of the country, incorporating the basic principles and strictly following the implementation strategies laid down. Specifically, the scheme is intended to provide support services for women who have to leave their homes for work in the fields during the working season. During the off-seasons, the women may look for intermittent and miscellaneous work opportunities, which again may be located far away from their homes.

The four models need to be used flexibly, keeping in mind local requirements, context, resources and women’s own needs and preferences. There may also be changes from season to season, depending on intensity of work, climate, and other factors. Of the four
models, three are existing schemes, incorporating positive modifications and improvements within the existing format. The fourth model, that of seasonal or temporary crèches, is being suggested in the context of the Rural Employment Guarantee Programme (REGP) being launched in 150 districts of the country. The four models are

1. ICDS—additional services for 0-2 years children
2. Mini-ICDS centres or outreach services for 0-2 years children
3. Creches run with grant-in-aid and
4. REGP - Seasonal or temporary crèches for short duration are required not only by seasonal agricultural labourers such as sugarcane workers, but also by women working on roads and public works, construction sites, quarries, brick kilns and by all the various works undertaken by Government departments as part of employment programmes. The new REGP would also come under this purview.

Here the number and age composition of the children cannot be predicted in advance. However, wherever there are children below three, it is likely that there should also be a certain number of children above three (up to the age of eight or ten) as the older children are usually engaged in looking after the younger ones and/or helping in the women’s work. Hence, no minimum number should be specified.

The model has to include at least two workers, one with exclusive responsibility for the below threes. The actual number needed at each place should have to be decided by the situation. If the child care workers are employed by a local authority with jurisdiction over a specified area, (for example, Panchayat or ICDS) then they can be shifted from place to place within that local area without much inconvenience.

The Departments of Agriculture in the States are expected to prepare a shelf of projects aimed at increasing productivity of land and labour, diversifying agriculture and thereby creating more work opportunities in the medium and long run by taking up water and soil conservation works, land development and other rural infrastructure
works. Other line Departments should also take similar action on horticulture, forestry, animal husbandry and allied subjects. These work sites are bound to attract large numbers of women, especially in the off-season, when the guarantee schemes are expected to be in full swing. The women generally bring young children to the work sites, thus offering both opportunity and need for effective and focused child care services. If this is not done, the children may be left in the care of slightly older siblings, either on-site or off-site, thus depriving the latter of their education.

Resource Allocation

Here it is attempted to indicate the likely order of resource allocation that may be needed for the enlarged programme of child care services, with special reference to children in the 0-2 age group. Details and cost of each model can only be worked out later.

The chosen criterion for costing is the cost per child per day, and the approximate number of children in need of the services.

At current prices, it is estimated that the cost per child per day would be a maximum of Rs.10.00 (or Rs.4,000 per child per year). This includes the following items - food, salaries, equipment, materials for cleanliness, hygiene, medical care, immunization and healthcare, developmental activities, training, supervision and guidance.

The total number of number of children 0-2 years who need such services, calculated on the Census (2001) data on number of children aged 0-4, and the likely number of mothers of young children in the work force, would be a maximum of 4 crore.

The total resources needed to provide every child in need in this each group would be of the order of Rs.16,000 crore.
It is suggested that the programme could be started in 20 most disadvantaged districts from the 150 districts selected for the REGP. The funds needed for this would be about Rs. 500 crore, including preparatory activities, during 2005-06.

8.7 Engendering Acts in areas of concern to women in Agriculture:

The proposed Act relating to Employment Guarantee should be gender-sensitive, with a definition of work which includes work in the areas of human development and keeping in mind working women’s needs in relation to child care and nutrition. The implementation rules relating to the Protection of Plant Varieties and Farmers’ Rights Act and the Biodiversity Act should also be engendered.

8.8 Institutional Mechanisms for Policy Oversight and Gender Audit

Though women continue to figure in the plans and programmes of the MOA, their presence is very thin in term of actual numbers and resource allocation. Women still are not fully recognized as productive agents in agriculture or as farmers. In order to ensure that women’s issues are not crowded out or marginalized in the sector, it is important to devise high level institutional mechanisms that would advise the Government on issues of policy, strategies, programmes etc. keeping the women’s interest in mind.

In order to provide effective support and monitoring of programmes for women in agriculture, it is necessary to constitute a high-level body combining political commitment to gender justice with expertise and committed advocacy. A National Board for a New Deal for Women in Agriculture, headed by the Union Minister of Agriculture should be set up. It should be co-chaired by Union Minister for Women & Child Development, Union Minister for Rural Development and Union Minister for Panchayati Raj. It should provide policy over sight and enable gender audit. Besides the concerned
Central Ministers/Ministries and State Government representatives, the Board should include -

a) Women farmers’ representative bodies

b) Representatives of panchayati raj institutions, academicians, experts from different disciplines and backgrounds, but with a common background of having worked with or a demonstrated interest in advancing the cause of poor women in land-based livelihoods in agriculture. These could include agricultural and extension specialists, representatives and leaders of women’s organizations, trade unions, banks and credit institutions like NABARD, women’s advocacy groups, etc.

c) Representatives of agricultural universities and other educational/technical institutions involved in extension, teaching and research on issues of women in agriculture.

d) Non-governmental bodies working at grass root level with farming women

e) Policy makers and analysts,

f) Media,

g) Rights-based and other groups working on issues of sustainable livelihoods and environment, bio-diversity.

h) National and State Commissions for Women

i) Women’s Universities.

j) Women’s Development Corporations

The Board could consider giving a certain direction to the broad band of programmes dealing with land and livelihoods (including anti-poverty, employment generation, safety nets etc.) by linking them up with gender and social equity and equality. Since such programmes are spread over many sectoral agencies and ministries, the Board should enable effective coordination amongst all these agencies.
While it should not be too large so as to become unwieldy and should meet at least once a quarter, it should represent all the stakeholders. Every State Government may be advised to set up a Gender Resource Unit or Cell in the Departments of Agriculture and Rural Development, linked with line Departments including Panchayati Raj, Women, Tribals, Forestry, Fisheries etc. These could be networked by a similar Gender Resource Cell recently set up by MOA.
CHAPTER – V
STRENGTHENING AND EXPANDING THE HORTICULTURE
REVOLUTION

Mobilising Untapped Opportunities

1. Horticulture is now widely recognized as one of the major components of the strategy for uplifting both the rural economy and national nutritional security. Diversification of Indian agriculture in the area of horticulture will enhance returns to the farmers, generate rural employment, increase farm exports and expand agro-industrial base, thereby contributing to higher economic growth. Recognising this, the Plan outlay for Horticulture in the VIII Plan was raised to Rs.1,000 crore (excluding the outlay for research to ICAR) as against Rs. 27 crore in the VII Plan (40 times more). The support continued in the IX and X Plans with allocations of Rs. 1,400 and Rs. 2,100 crore, respectively, including the Horticulture Technology Mission for the North East Region and three hill States of Western Himalayas and the Coconut Mission.

2. The above mentioned schemes of the GOI provided liberal assistance as subsidy for the development of horticulture crops such as fruits, vegetables, ornamental crops, plantation crops, spices, medicinal and aromatic crops, mushrooms, beekeeping etc. for improving productivity and overall production, reducing post harvest losses and also for enhancing exports. Assistance was provided for major activities such as area expansion under individual crops, multiplication of seed and planting material, improvement of productivity of the area already under these crops, use of plastics (drip / sprinkler irrigation, green/poly houses, plastic mulches), infrastructure for post harvest management (PHM) of the crops, training and demonstrations in new technologies etc. Some State governments also made special efforts to promote horticulture.

3. The above efforts had led to the expansion in exports of horticulture products, faster promotion and use of drip irrigation, establishment of green houses, promotion of cut flower production, exploitation of hybrids in vegetable production, adoption of beekeeping as an essential input also for fruit and vegetable seed production, development of infrastructure and adoption of improved techniques for PHM and processing in some pockets. Further, horticultural consumption by the middle and upper class population increased tremendously.

113
4. The UPA Government has accorded high priority to this sub-sector by announcing the launching of the National Horticulture Mission (NHM). Through this initiative, the Government has affirmed its faith in horticulture development for improving rural economy through diversification of land use and improving productivity and marketing. In compliance with the above, the Department of Agriculture and Cooperation has now submitted a detailed proposal on the NHM for a total outlay of Rs. 21,699 crore to be used during the coming 7 years to achieve the Stated goal of raising the total production of horticultural commodities to 300 million tonnes.

A “Business as Usual” Approach will not Help to Realize the Goal

5. As seen from table 1, during the past decade, while overall production of horticultural crops improved by 27.1% and the area expanded by 27.7%, the overall productivity showed little change. As a matter of fact, the productivity of fruits and plantation crops declined during the 10-year period. However, vegetables showed a marginal increase, while it was comparatively higher only in spices. It is, therefore, clear that huge investments made in the two Plan (VIII & IX) periods did not help to make a major dent in the productivity (except in spices).

Source: National Horticulture Board
6. Little is known of the benefits reaching the small and marginal farmers and landless agricultural workers. The old and senile plantations continue to remain neglected, bringing down the national averages of productivity but occupying prime fertile land area all over the country.

7. Only a few States, such as Maharashtra, Karnataka, Andhra Pradesh, and Tamil Nadu have registered excellent progress, especially in the production of fruits. The regional disparity in horticultural development has become much more pronounced now, despite the strong potential all the regions possess. Several States have not benefited from the opportunity and the investment made.

8. One of the major reasons for low and skewed impact can be attributed to the absence of prioritization of developmental activities in each State based on location, potential, needs, aspirations and capabilities for fund utilisation. This may be attributed to the non-participatory mode of identifying the priorities and resource deployment. Consequently, support was provided for all crops and for all components, thus spreading the support too thin to make any tangible impact.

9. Serious mismatch between production and consumption continues although there is no reliable data available to estimate the success achieved during the last 10 years in reducing post harvest losses. The estimates of monetary losses being incurred in the country keep rising at regular intervals, as evident from the four reports brought out during the past decade: 1993-94 = Rs 8,000 crore (Min. of Food Proc.); 1996-97 = Rs. 25,000 crore (Mckinsey Report); 1999-00 = Rs. 50,000 crore (Anon.) and 2004-05 = Rs. 85,000 crore (Directorate of Marketing, Maharashtra). The huge investments made not only by the Department of Agriculture and Cooperation, but also by the APEDA, NCDC, NAFED, Ministry of Food Processing etc. have thus not succeeded much in reducing the staggering post harvest losses. No authentic data are available on the reduction in losses, if any, achieved due to the infrastructure created, improved PHM technologies promoted and several policy initiatives taken for streamlining the systems involved.
10. All investments and efforts made for improving PHM have ended at the storage level of bulk quantities of a few commodities, with no care taken at the retail level. Consequently, the fresh produce continues to be sold in open stalls, roadside kiosks, carts, footpaths etc. causing serious loss in quality of the produce besides adding to the PH losses. A recent FAO study on handling of apple in HP State showed that the fruits record a pressure of 18 - 20 lb/ sq.in at harvest which gets reduced to 5-6 lb/ sq.in when sold in retail, as a result of the time the fruit takes to reach the retail market. Both producers and consumers suffer due to deterioration in quality between the farm gate and the consumer.

11. The above trends of stagnant or declining national productivity and high post harvest losses point to two main things: either the NHB data are not based on methodologies which can capture the real situation or the investments have failed to produce the intended outcomes (outputs counted in terms of subsidies distributed and additional hectares planted to horticultural crops may not reflect the real impact).

Lessons Learnt from the Technology Mission for the North East Region

12. The TM for the North East Region (NER) is now in its 4th year of implementation. The Mission consists of four Mini Missions (MM) viz. MM I for improved seed and planting material, technology refinement and adoption, handled by the ICAR; MM II for improving crop production and productivity covering support for area expansion, creation of water resources and on-farm water management, multiplication of seed and planting material, promotion of organic farming, use of bio-fertilizers, IPM, INM, tissue culture, plant health clinics, disease diagnostic and plant tissue analysis labs., training of farmers etc. handled by the DAC; MM III for post harvest management, marketing including export by Directorate of Marketing and APEDA; and MM IV for processing and product development under the control of MOFPI.

13. Review of the Mission activities shows a large gap between the original concept and actual implementation in the field. Linkages among the four MMs are weak. Each MM is working independent of the other under the control of their respective administrative agencies.

14. Other gaps and weaknesses awaiting redressal are as below:
14.1 Targets for annual area expansion under different crops and the varieties to be promoted are fixed arbitrarily without any long term planning of the total area to be put under individual crops and without consultation with the research units located in the States.

14.2 Every State has been allotted financial support for all crops and all the components, irrespective of the commercial potential and need suggesting the lack of an agro-ecological and comparative advantage approach in priority setting.

14.3 Production of planting material is yet to take off within the States and hence procurement is done from outside the State from untested sources; a permanent damage thus being inflicted because of the perennial nature of the fruit species.

14.4 Procurement procedures for seed and planting material adopted leave considerable doubt about the quality of the planting material being used.

14.5 Varieties / hybrids promoted are chosen arbitrarily mostly those available in the market, irrespective of the adaptability and superiority.

14.6 Implementation of several cost-intensive components are contracted out on turn-key basis, a few of them being taken up on joint venture basis in partnership with private sector.

14.7 Assistance for highly technical units such as plant tissue analysis lab, disease forecasting lab, tissue culture units, plant health clinic etc has been provided to all States irrespective of the needs, competence of the staff and availability of appropriate technology for using the facilities for the farmers.

14.8 The R&D activities taken up under MM I are not need-based to provide technological support for the crops and activities identified for development by the States.

14.9 Infrastructure for PHM including marketing and processing is planned without any relation to the total production targeted at a given point of time.
14.10 The PHM units created so far are better handled under SHGs or the private sector,

14.11 Subsidy for inputs for newly planted area is not used effectively nor verified; the States are seeking subsidy hike from the current level of Rs 13,000 to Rs 30,000 per hectare (and this has already apparently been agreed to as judged by the rate used in the NHM project document), and

14.12 Absence of field monitoring, inadequate trained staff in the departments and urgent need for training of farmers.

RECOMMENDATIONS: THE PATH AHEAD

15. In order to achieve the goals of the horticulture-led agrarian prosperity and to realize the objectives of the National Horticulture Mission, the following recommendations related to policy, institutions, infrastructures, organizations and implementation are made:

A. Public Policy

16. **National Horticulture Council:** Given the goal, interdisciplinary nature, size and high pervasiveness of the horticulture-led nutritional, agro-ecological and livelihood security, an apex level national body (National Horticulture Council) may be established with the Union Minister of Agriculture as its Chairman and Union Ministers of the other concerned Ministries, such as Ministries of Rural Development, Commerce, Environment and Forests and Science and Technology as members. A Steering Committee of the National Horticulture Council, headed by Agriculture Secretary with counterparts of the concerned Ministries and eminent representatives of professionals and technical experts, private sector, industry, NGOs and farmers may be constituted to ensure effective, timely and synergistic implementation of the programmes and activities. Counterpart bodies may be established at the State and district levels. At the grassroot level, panchayats, other grassroot institutions and SHGs should be suitably empowered and interlinked. Farm Schools may be established in the fields of outstanding horticultural farmers.
17. **Socially differentiated approach**: The wide variety of horticultural species have been exploited differently by different sections of the society. For instance, organized commercial fruit production and plantation has been pursued mostly by larger scale and resource-rich farmers. Small farmers are generally more involved with intensified vegetable and flower production, whereas tribals have greater affinity with medicinal plants and indigenous fruits and vegetables abounding in forest areas. However, national and international experiences show that, if organized in groups, the small farmers could effectively adopt and prosper from commercialization of fruits as well as other such horticultural commodities. Given that 80 percent of the Indian farmers are small (possessing less than two ha.) and marginal, explicit policy provisions must be made for resource poor farming families, who have generally been excluded from the past horticultural development process. Programmes and institutional support should be designed with focus on the small and tribal farmers.

18. Horticulture has the potential of engaging rural women, both skilled and unskilled, in gainful employment and consequently for their emancipation through resultant economic independence. Women are best suited to handle activities like vegetable and flower seed production, production of hybrids, floriculture, tissue culture, grading, sorting of fresh produce, preparation of processed products etc. Assistance for such activities should therefore be made subject to the engagement of women. Training of women in different operations should receive priority and be supported under the NHM. The Mission should also help the States to promote setting up of women SHGs for strengthening institutional base at the village level on the pattern in place in Assam and Kerala. Engendering the Horticulture Mission is a priority task.

19. Consumption of horticulture products (fruits and vegetables) is acknowledged globally as a sustainable source of nutritional security to the masses, particularly the children and women. The country’s economic prosperity would not make it an advanced nation unless the masses are healthy and free of the effects of malnutrition. The revolution should, therefore, pay appropriate attention to promoting consumption, particularly in the rural areas through promotion of backyard / kitchen gardens and development of easy to use household products, backed by a strong awareness campaign. Enhancing consumption in the urban areas would be possible
through price rationalization and better retailing to reduce losses and preventing decline in the quality. Social marketing techniques should be promoted.

20. Lately, the corporate sector is showing interest in horticultural farming – production, processing and marketing and is undertaking contract farming arrangements, including tie-up with small farmers’ groups. Explicit codes of conduct for all the partners involved in contract farming arrangements should be developed. The government should enact necessary regulations on contract farming, keeping in view the interest of the weaker partner – the farmer. It should ultimately be a win-win situation for all stakeholders.

21. **Risk Coverage:** The National Agriculture Insurance Scheme (NAIS) which has the coverage of all food crops, oilseeds and annual horticultural/commercial crops – sugarcane, cotton, potato, onion, chilly, turmeric, ginger, jute, tapioca, annual banana and annual pineapple is in operation since 1999-2000. The Scheme does not cover perennial horticulture crops which suffer from the wide fluctuation in yield, proving to be a major source of distress to the farmers.

22. In the year 2000, a Committee was constituted under the Chairmanship of the Economic and Statistical Adviser, Govt. of India comprising Joint Secretary (CR), Director (IASRI), GM (GIC) as members to examine the scope of coverage of perennial horticultural crops under the NAIS. The Committee deliberated upon the range of issues concerning insurance scheme of perennial horticultural crops and recommended for insurance of horticultural crops on pilot basis in selected districts of some States. Accordingly, the operational modalities of pilot projects were worked out and a pilot project was put in operation since 2002-03 season. As the production of perennial horticultural crops is cyclical in nature, it suffers from low yield once in 3-4 years. This fluctuation in yield needs a high rate of premium. The actuarial premium rates are given in the following table:

23. As per the Scheme, it was voluntary for all farmers with subsidy of 50% to small and marginal farmers. Despite 50% subsidy, the premium rates payable by farmers are high and the pilot project remained virtually a nonstarter. Experiences of other countries should be analyzed and the pilot programme needs to be carried out more systematically to reach satisfactory conclusion and action plan.

B. Public Action

24. Ensuring Convergence, Synergy and Effectiveness of the National Horticulture Mission: The sectoral Missions of the NHM, proposed to be executed by different ministries/departments should be designed and implemented in an integrated and synergistic manner, headed and coordinated by one National Director. The pitfalls of the NER Horticulture Technology Mission must be avoided. There should be a greater sense of accountability at all levels.

25. The Mission’s success is not to be judged by the amount of the budget spent but should be measured in terms of verifiable outputs such as technologies, services, human skill and resources, infrastructure, institutions, networks, linkages, knowledge and awareness geared towards achieving the goal of enhanced productivity, quality, income, profitability, competitiveness and inclusiveness consistent with ecological and livelihood security of the poor. Using a set of powerful socio-economic and agro-ecological indicators, the Mission should regularly monitor the outcomes and progress and undertake mid-course corrections, if needed. The NHM document should be redesigned in a participatory mode with built-in strong mechanisms of monitoring, evaluation, outcome assessment and mid-course corrections.
26. Horticulture enterprise covers a large number of commodities and encompasses an equally large number of problems / constraints of diverse nature and magnitude. Hence, putting all these into one Mission would be too much to handle, given the type of management set up we have in the States. The Mission should either cover a few major and commercially important commodities, or separate Missions should be launched for (i) Fruits & Vegetables, (ii) Floriculture, (iii) Medicinal and Aromatic Plants, (iv) Plantation Crops, and (v) Spices with well defined mandates. Each of these Missions should be highly selective and cover selected crops and specific activities.

27. **Focus On Post Harvest Management (PHM), Processing And Marketing — Bridging The Disconnect Between Production And Profit**: Emphasis under each commodity should start with investments in infrastructure for PHM, regulated markets, Agri-export zones, processing and modernized retail outlets to be owned by growers’ cooperatives or associations, SHGs, Farm Management Committees, private sector etc in a participatory approach, with government interventions directed mainly to streamlining the policy framework including food safety regulations and monitoring roles. Experience has shown that NDDB’s model of fruit and vegetable retailing with backward and forward linkages has been quite effective in Delhi. This could be expanded to cover all metros to begin with and extended to other urban areas subsequently. In order to promote social marketing, cost effective modes of storage and distribution of horticultural products, such as making fruit juices available through dispenser units may be adopted. Mother Dairy Units can also add the sale of fruit juices. Successful models of group and producer centred marketing such as Mahagrapes, Apni Mandi, Hopcom and others should be actively promoted by the NHB. Processing and marketing of India’s unique horticultural blessings, such as seabuckthorn from Ladakh (popularly known as Leh berry) should receive special attention.

28. Planning for infrastructure for PHM should be done for each production zone, adopting the well known concept of ‘Packing House’ successfully adopted by the Grape Growers’ Association, NDDB etc. It would mean setting up of a chain of Packing Houses in each production zone, equipped with facilities for collection, cleaning, grading, packing, pre-cooling,
storage and transportation to the modernised wholesale markets such as the one coming up in Bangalore through NDDB. Adoption of this strategy would call for immediate amendment to the APMC Act by each State to decentralize the system and permit marketing by other players for achieving the ultimate goal of ensuring better returns to the growers and reasonably good quality products to the consumers.

29. Appropriate regulatory mechanisms, including SPS, would be required for trade and export promotion, multiplication and distribution of quality seed/planting material, quality control of inputs being used, operation of ‘contract farming’, packing houses, exports, etc. With free trade there are chances of the introduction of invasive alien species of insect pests, pathogens and weeds which may threaten the livelihood security of the people. Therefore, States should initiate steps along with the Ministries of Agriculture and Commerce and ICAR to create necessary infrastructure for preventing the unintended introduction of serious threats to our crops. The Mission should promote human resource development in horticulture for generating skilled manpower trained in different horticultural enterprises, enrolling educated rural youth for gainful employment and for promoting precision and knowledge-based horticulture. Farm Schools can play a valuable role in skill empowerment.

30. Training and skill development in processing of fruits and vegetables and organizing cooperatives for production and marketing of processed products need to be undertaken on a large scale. Similarly, organized high-tech processing industries should be set up both in cooperative and private sectors for domestic and export markets. To achieve this, the emphasis should be on strengthening of existing processing facilities, development of cultivars suitable for processing, promotion of private/cooperative processing units and demonstration of processing techniques for cottage level industries.

31. **Creating Reliable Databases:** The Mission must address on priority basis the issue of strengthening databases for all horticulture crops and their products, market arrivals, price trends, etc. This would call for a multi-agency approach for standardizing methodology, including use of satellite imagery and other innovative methods for data collection, compilation and interpretation including yield forecasting, and devising a viable system at block, district and State levels. A reliable database becomes essential for efficient trading, including exports.
32. **Regionally Differentiated Approach:** Agro-ecological and socio-economic specifications and endowments of different regions should be matched with the most appropriate crop and farming systems leading to enhanced productivity and sustainability. For regulating support for production related activities, demarcating “Production Zones” for each commodity covering contiguous areas already under these crops and that targeted for expansion through diversification of the land use should form the basis for planning in each State. The arid, semi-arid and temperate zones apart from the NER should receive priority attention due to large concentration of small holdings, low per capita income from agricultural enterprises and large untapped potential for horticulture development. For example, the cold desert region of Ladakh offers great potential for the production of apricot, sea buckthorn, etc. Each zone should have a long term plan for the crops and their varieties to be promoted so as to back it up with appropriate PHM infrastructure and systems.

33. **Research and Technology Development Thrusts Including Flow of Quality Planting Material:** The R&D efforts did not keep pace with the rise in demand for improved technology which rose phenomenally since the VIII Plan. The National Agricultural Research System (NARS) was neither ready for it nor fully equipped in the initial stages, forcing entrepreneurs to depend on imported technologies. Further, the research in horticulture has to be reoriented to make it need-based or demand-driven to provide immediate relief to the farmers / stakeholders, reduce the cost of production and make Indian horticulture globally competitive. The ICAR / SAUs would need to undertake major reforms in research planning, prioritize the needs for new technologies, overhaul the research agenda in horticulture accordingly, actively involving other research institutions both in public and private sectors. The need-based technologies would be in the areas of improved varieties / hybrids resistant to biotic and abiotic stresses, faster and cheaper propagation techniques, IPM, INM, organic farming, resolution of chronic plant health problems, soil fertility and water management, rejuvenation of old plantations, high density plantings, PHM for domestic and export markets, new products etc. The Mission should trigger such a change and provide substantial support to technology generation, refinement and adoption.

34. The fruit industry is plagued with some perennial disease problems viz. malformation, alternate bearing, spongy tissue of mango, decline in citrus, wilt in pomegranate, sapota seed borer, coconut wilt and sigatoka in banana. Need-based evaluation of genetic resources, use of
indigenous nutrition-rich fruit species, conservation and use of rich indigenous knowledge are priority areas. Rejuvenation of old and senile orchards and establishment of an effective system to ensure timely flow of quality planting material of desired varieties in desired quantity should be among the top development priorities.

C. Small Farmers’ Horticulture EStates: Integrated Institutional Structure for Production, Processing and Marketing

35. Generally, small and marginal farmers have not benefited particularly from the fruit revolution in the country. This is primarily due to their poor competitiveness both at the production and post harvest phases. However, it is now well established that small and marginal horticulture farmers in particular will excel in improving productivity once they are assured of quick and easy disposal of their produce at reasonable returns. In clusters, specially in villages adjoining large consumption centres, small farmers should be helped to organize themselves as Small Farmers’ Horticulture EStates in the form of SHGs covering an area of 200-500 hectares. SHGs may undertake specialized activities like seed production, tissue culture propagation, vermiculture, biofertiliser, biopesticides and e-commerce. These should be duly empowered through enhanced access to modern technologies, formal credit and marketing. Since horticultural commodities are mostly perishable, these need effective infrastructure support in the areas not only of production, but much more for processing, storage, transportation and marketing. The group action will confer on the small farmers the power of scale both at the production and post harvest phases of the horticultural enterprises.

36. The National Horticulture Board (NHB) and the proposed National Horticulture Mission should give high priority to the establishment and effective functioning of the eStates. Horticulture is a proven technology for empowering even resource poor farmers who could produce high value crops at low cost. The Mission should actively promote this technology for enhancing rural livelihoods. In order to ensure right quality and yield, fertigation techniques should be promoted along with the low cost green houses. The Small Farmers Horticultural EStates should be assisted by the Mission in creating common facilities for post harvest handling, storage and marketing assistance. The market yards could also house agri clinics and agri business centres, including ICT based Knowledge Centres to enhance awareness for
increased consumption of fruits and vegetables as well as to have access to reliable inputs and
distribution channels. Effective local SHGs should be promoted to ensure supply of genuine and
healthy planting material. Also seeds and planting materials of such varieties which are suitable
for processing will have to be provided to farmers in areas where production and processing are
linked. The expertise of CFTRI should be fully mobilized in PHM.

37. The Small Farmers’ Horticulture Estates should receive special assistance for
rejuvenation of old plantations on high priority. In addition, development of water resources, on
farm water management, drip irrigation, training and demonstration of improved technology
should be emphasized. Wherever possible, the public sector extension services should be
supplemented or join hands with private sector extension services to improve the overhaul access
on the part of the small and marginal farmers to modern technologies and appropriate
knowledge. The Krishi Vigyan Kendras of the ICAR may suitably be transformed into Krishi
and Udyog Vigyan Kendras and likewise the ATMAs should also give due emphasis to the
promotion of group processing and marketing in their extension activities. Since the role of
precision horticulture will increase in the globalized world, the role of value added information
(knowledge) to all the stakeholders in the production-processing-marketing-utilization chain
can hardly be overemphasized. A quality literacy movement should be launched to sensitise
farm women and men on issues relating to pesticide residues and Codex Aalimentarius standards
of food safety.

38. Use of IT for horticulture development is yet to receive due support. Its usefulnes for
creating databases cannot be overemphasized. Besides, its scope should be exploited for assisting
in the implementation and monitoring of the progress in each district. Major use should be for
faster transfer of information on improved technologies, sources of supply and market outlets.
Pest and disease diagnosis for which the technologies are already available in hard copies would
need to be digitized and transmitted to the Community Information Centres being or to be set up
in each block and these should be linked with Village Knowledge Centres.

39. Spreading the successful experience of Maharashtra: Horticultural progress in the
State of Maharashtra has been truly revolutionary. The area under fruit crops in the State
increased from 2.42 lakhs in 1990 to nearby 13 lakh ha. in 2002 and the yield has almost doubled to about 15 tons per ha. This was essentially due to the steps taken by the then Chief Minister of the State (Shri Sharad Pawar) to link horticultural development with the Employment Guarantee Scheme. Creation of various infrastructure facilities like horticulture nurseries, micro irrigation, cooperative institutions and strengthening of research and institutional support were instrumental in achieving the success. In particular, the experience of Baramati in Pune District is worthy of emulation. In this area, end-to-end connections have been established in improving productivity and quality through technology transfer, post harvest management, prevention of losses, processing facilities, market information and finally export.

40. Learning from successes will help to purchase time. Therefore, we recommend the following steps:

40.1 Organise visits by women and men taking to horticulture to other horticultural “bright spots” like Baramati. **Farm Schools** may be established in the fields of horticultural pioneers. Farmer to farmer learning is the most effective method of confidence and competence building.

40.2 Link horticulture with the National Food for Work and National Rural Employment Guarantee Schemes.

40.3 Revitalise the National Horticulture Board in order to enable it to function like the National Dairy Development Board, providing critical support to small growers, empowering them in relation to the economies of scale through the Small Farmers’ Horticulture EStates movement as well as in access to good seeds and planting material and in post harvest processing and marketing.

40.4 The proposed National Horticulture Council (NHC) may monitor progress not merely in terms of money spent, but more importantly in terms of progress made in enhancing productivity, quality, value addition and prevention of post harvest
losses. The NHC should also ensure that all the research and development programmes in horticulture are engendered.

Financial Resources

41. Rs. 21,699 crore is already proposed under the NHM for the next seven years. The resources may be reallocated according to the priorities suggested in this Report, especially the following areas:

41.1 Organization of Small Farmers’ Horticulture Estates
41.2 Post harvest management, processing and marketing
41.3 Production and distribution of quality seeds and planting materials
41.4 Imparting quality literacy.
CHAPTER-VI

ENHANCING COTTON PRODUCTIVITY, QUALITY AND GLOBAL COMPETITIVENESS

Uncommon Opportunities and Challenges for Cotton-Based Livelihood and Income Security

1. Over four million farmers in India grow cotton as the main source of their income and livelihood. The textiles sector, which is primarily based on cotton fibre, is the largest employer and income provider in India, second only to agriculture. It employs close to 82 million people - 35 million in textiles and 47 million in allied sector. The total employment by 2010 is expected to reach 94 million people.

2. With the coming to an end of the multi-fibre arrangement on 1st January, 2005, our cotton producers, weavers and the textile industry will encounter both new opportunities and threats. The Vision Statement of the Indian Cotton Mills Federation (ICMF) for the textiles sector released in August, 2004, States that by the year 2006, the Indian textiles and apparel industry, can achieve a potential size of US$ 85 billion from the current size of US$36 billion, of which the domestic market potential would be US$ 45 billion and the exports would comprise the remaining US $ 40 billion. Consequently, over 35 percent of India's exports would be from textiles. This leap will thus be fuelled both by rise in domestic consumption and almost quadrupling of exports primarily due to discontinuing of the quota system.

3. Value-addition along the entire chain, starting from the production of quality cotton to ginning, spinning, weaving, knitting, processing and garmenting must be the key strategy for achieving the Vision. Production of cotton fibre would need to be increased by 75 percent, from the current level of about 200 lakh bales to 350 lakh bales in 2010. Productivity, quality, value addition and marketing revolution through synergistic interaction among all stakeholders is thus urgently needed to enhance efficiency of cotton production, processing and marketing to benefit from the opportunity and to obviate the threat.
4. Oscillating around 300 kg/ha (lint yield), India's average yield of cotton has remained one of the lowest in the world, being less than half of the world's average and less than one-third of China's average. Moreover, our lint quality is poor and often, due to one or the other reason, including those due to SPS concerns, it fails to meet the international standards. Thus, India’s cotton productivity and cotton-based textiles competitiveness is low. With a “business as usual” approach, our competitiveness will further decline in the liberalized cotton market, thus threatening the collapse of this vital sector of our economy and employment.

The Problems Needing Urgent Attention

5. **Low Cotton Yields and Wide Yield Gaps:** As mentioned earlier, India’s cotton yield has remained stubbornly low. Moreover, primarily due to the monsoon and market (prices) uncertainties, the yield has fluctuated widely from year to year. Even in the predominantly irrigated tracts, such as the North Zone, the yield hovers around only 400 kg/ha, resulting in one of the lowest water productivity. Consequently, even though the country accounts for about 25 percent of the world's area, its share in the world production is only 13 percent. On the other hand, China, with half the area under cotton cultivation produces 1.5 times the amount of cotton and has 1.5 times the world market share. Moreover, the gaps between farmers' average yields and realizable yields and between the realizable and potential yield in the three major cotton-growing zones of the country are rather large.

6. **Deteriorating soil health, poor productivity, declining factor productivity and profitability:** Due to increasing mismatch between the agro-ecological capacity and intensification of cotton production, increasing soil fertility imbalance, especially micronutrient deficiencies and decreasing efficiency of water and nutrient use, the productivity and growth rates of total and partial factor productivities have been declining. Methods of cultivation and irrigation presently employed also result in a very high consumption of water in cotton cultivation, which can be reduced by more than 50 percent by adopting appropriate technologies. Being a rainfed and highly sensitive crop to biotic and abiotic stresses, coupled with the gamble in the market place, the risk factor is extremely high, at times causing extreme distress to the
cotton farmers, especially in Andhra Pradesh and Karnataka (cotton farmers constitute the majority of the suicide-committing farmers).

7. **High biotic stresses and excessive use of pesticides:** Cotton is an attractive host for several pests. Although the pest scenario changes from year to year, depending on weather conditions, bollworms remain the most important yield limiting factors and American bollworm takes the prime position. If not protected, yield losses may be as high as 40 to 100 percent, depending on the pest intensity. In order to minimize the losses caused due to insect pests, the farmers resort to calendar sprayings of highly toxic insecticides, accounting for about 50 percent of the total cost of production. Cotton consumes over 40% of the total quantity of pesticides used in the country. More importantly, the practice has resulted in the emergence of resistance to the frequently used pesticides, besides causing serious environmental pollution and creating health hazards.

8. **Uncertainty about cotton production and trade:** India's cotton production fluctuates widely from year to year. Until the last year (2003-04), the all time high was at 178 lakh bales in 1996-97, rising from 139 lakh bales in 1994-95 and again dipping to 136 lakh bales in 2002-03. On the other hand, the country's cotton consumption has been increasing annually by 4%. In most years, the consumption has outstripped the production, necessitating an annual average import of about 20 lakh bales, costing over Rs 2000 crore, during the past few years.

9. However, fortunately, during the last year and this year, primarily due to yield increase, from around 300 kg/ha for several years to 384 kg/ha in 2003-04 and to 402 kg/ha in 2004-05, the domestic production correspondingly increased to 177 lakh bales and 213 lakh bales (estimated) respectively in the two years. Consequently, the imports in 2003-04 declined to 8 lakh bales and, more importantly during the same period, India exported 8 lakh bales of cotton, whereas our exports had not reached even one lakh bales for several years in the past.

10. In the context of the abolition of quotas by the end of this month (December, 2004), various segments of the textile industry in India and abroad are reported to be undertaking expansion and modernization of their production facilities. This is bound to expand the domestic
consumption as well as exports. A substantial proportion of the expanded cotton production will be used domestically to meet this encouraging trend. During this year, 2004-05, the domestic consumption is expected to reach 190 lakh bales and the production is likely to reach 213 lakh bales, necessitating a vigorous push for achieving remunerative net export of about 20 lakh bales, a quantity which India has never exported in the past. Unfortunately, international prices are falling.

11. **Low availability of quality seeds and other inputs:** Non-availability of adequate quantity of quality seeds and other inputs at the appropriate time is the foremost constraint. Nearly 50% of the total cotton area is under hybrid varieties and the remaining 50% under "open" pollinated varieties. While the private sector is able to meet the requirement of the hybrid varieties, the availability of seed of cotton varieties is limited to about 80,000 to 90,000 quintals only against the total requirement of 4.2 lakh quintals. Moreover, often the purchased seeds, fertilizers, biofertilizers, pesticides, biopesticides and bioagents are spurious, uncertified and nonstandard, thus creating economic, social and environmental crisis. In irrigated areas, the farmers invariably complain of the untimeliness of canal and electricity dependent water availability causing uncertainties.

12. **Poor lint quality and high contamination:** Poor fibre attributes, rapid deterioration of fibre quality of hybrids with successive pickings, high trash content (4 to 7%) and contamination have seriously been depressing the lint and yarn quality. India is capable of eliminating these bottlenecks and must ensure supply of quality cotton to its mills. Unnecessarily high multiplicity of varieties comprising nearly 300 varieties of highly variable fibre qualities predisposes the cotton system to contamination and non uniform yarn quality from the field to the ginning and pressing factory levels. The rapidly modernizing textile industry, such as increase in the speed of spindles, demands significant changes in the qualitative requirements of raw cotton. Today in addition to fibre length, the industry needs fibres with higher strength and better micronaire to withstand the high RPM.

13. **Unsatisfactory extension services and linkages:** The persisting and widening yield gaps point to the poor extension services for transfer of proven technologies and knowledge. High
cotton yield countries, such as Brazil, China, Turkey, etc. have dedicated cotton extension staff with clearly defined coverage of area and activities. In China, contract extension services are extremely effective and a close interaction and contact is maintained between the farmer and the extension agent. None of these arrangements exist in India. The extension workers are not adequately trained in the practices, approaches and strategies for their transfer and adoption of new technologies such as Integrated Pest Management (IPM), International Nutrient Management (INM), Insecticide Resistance Management (IRM) and Genetically Modified Organisms (GMOs). Specifically tailored training programmes are missing. Proven successful experiences such as Farmers’ Field Schools are operational only in patches.

14. Besides the poor quality, the points of distribution of the inputs are rather scattered. The role of cooperatives, SHGs, agriclinics and information centers have been negligible in promoting efficient production and distribution of cotton. Barring a few recent initiatives, the public-private (including NGO) - farmer linkage in technology transfer, information sharing and overall extension activities has been unsatisfactory. The monitoring, evaluation and mid-course corrections need to be improved.

15. **Highly inadequate credit and other institutional support:** Most cotton farmers are small and marginal and generally resource-poor. On the other hand, cost of production of cotton, especially the costs of hybrid and Bt. Cotton seeds and of pesticides, are very high and beyond the capacity of majority of the farmers. The formal credit availability is highly inadequate and the arrangements to access it are quite cumbersome and time-consuming. Therefore, most farmers turn to easily accessible non-formal sources of credit, but at high rates of interest and with other associated unfriendly agreements. As over 70% of the crop is grown under rainfed and monsoonal uncertainties, cotton production is highly risk-prone. In the absence of satisfactory crop insurance mechanisms, the growers' vulnerability is exacerbated and they generally land into traps of layers of debts. So much so that sometimes the economic and social burdens become unbearable and the farmers resort to the extreme step of committing suicide.

16. **Unsatisfactory Pricing and Marketing:** The current slump in cotton prices both in the domestic and international markets has caused serious concern and distress in the minds of
Indian cotton farmers as their increased production holds little promise for their income and profitability. The situation is tricky also for the cotton mills as with globalisation and with the abolition of the quota restriction from January 1, 2005, they would be free to procure their raw materials at competitive prices from anywhere in the world, which is already happening and is further depressing the domestic prices. However, realizing that the farmers and the industry are interdependent and neither can prosper at the expense of the other, short and long term mutually supportive interventions and measures are required for the mutual benefit of farmers, industry and the consumers.

The Way Ahead: Critical Interventions

A. Public Policy:

17. **Establishing a National Cotton Council: an apex coordinating mechanism:** The Centrally Sponsored Scheme of Technology Mission on Cotton (TMC), comprising four Mini Missions (MM) and operational since 2000-2001 in all the 13 cotton growing States seeks to address the various issues by integrating different aspects of cotton, namely research, extension and development for production; development of market infrastructure/yards; and modernization of ginning/pressing factories respectively through MM-I, II, III and IV. Mini Mission I is implemented by ICAR, MM-II by the Department of Agriculture and Cooperation and MM-III and MM-IV by the Ministry of Textiles.

18. The performance of the TMC has been a mixed one. Mini Missions III and IV, seem to be on track to achieve their physical targets of renovation and modernization. The outcomes and impacts of MM-I and MM-II are not quite discernible, although during 2003-04 and 2004-05 yield and production had increased, it is attributed mainly to good prices, good weather, increased area under Bt. Hybrids and increasing involvement of cotton mills and the private sector in technology transfer. There was little perceptible increase in the supply of quality seeds of open-pollinated varieties and in the adoption of the INM, IRM and IPM technologies beyond the "project areas."

19. Unfortunately, the four Mini Missions are tending to operate in isolation of each other, with no integration of efforts and approaches. As a result, the expected positive interaction
effects are being missed out. Some of the participating State Governments have neither allocated the apportioned 25% of the budget nor have they spent any Central Government Fund, especially under MM-II which accounts for about 75 percent of the TMC funds. Yet, the production in these States has moved up. The "Mission spirit" of partnership and leveraging interactions is missing and the programme is generally running in the longstanding Intensive Cotton Development Programme (ICDP) mode.

20. The TMC at the Central level is supposed to receive its direction, control and integration from its National Steering Committee constituted for the purpose. At State level, a counterpart State Steering Committee is to be in place. Although well intended, the committees have not been effective in providing the necessary integration of Mini Missions and drive to the TMC, as a whole. In order to overcome this problem, on the lines of the International Cotton Council, a National Cotton Council comprising representatives of farmers, textile industry, NGOs, public sector and other major stakeholders, should be set up under the Chairmanship of the Union Minister for Agriculture, with the Union Ministers of Textiles and Commerce serving as Co-chairs. The Council will guide the Mission in taking the right steps at the right time and place. Among other things, the Council should suggest as to how productivity and quality can be improved and the cost of production brought down through enhancing the pace of progress in factor productivity and guide the nation's cotton economy to remain buoyant in the globalised world, with special consideration of the needs and aspirations of millions of small cotton farmers, weavers and their families.

21. Remunerative prices to the farmers and farmer-centred marketing: The cotton production during 2004-05 is estimated to be 213 lakh bales. The carry forward stock from 2003-04 is 24.5 lakh bales. Thus, total availability of cotton is placed at 237.5 lakh bales during 2004-05. As against this, the total demand including both mill and non-mill consumption even if placed at about 200 lakh bales will leave a stock of 37 lakh bales. Maintaining a cushion of about 17 lakh bales, the exportable surplus stands at 20 lakh bales. This domestic glut is further aggravated by the glut in the international cotton market. As per the International Cotton Advisory Council, the world cotton production is estimated at 24.14 million tonnes during 2004-05 against demand of around 21.97 million tonnes leaving a stock of 9.87 million tonnes. The resultant effect is the fall
in cotton prices in world (Cotlook Index) from 70 cents per pound (454 gms) in 2003-04 to 45 cents per pound in December, 2004. The price of cotton in India also decreased from about Rs 2500 per quintal at the beginning of the season to less than the MSP of Rs 1760 - Rs 1960.

22. The landed price of cotton (lint) is somewhat lower than the price prevailing in the domestic market. In order to protect the cotton farmers throughout the country, Import Duty, which is 10% at present, needs to be enhanced to at least 30% to restrict the cheap import, particularly of the category most produced and used domestically. The import duty for the extra long fine cotton may be maintained at the current level of 10% so that India's competitiveness in yarn export may not be jeopardized. The mills in collaboration with CCI and APEDA need to assess the count-wise requirement and consumption to facilitate national policies and action required in cotton sector and should proactively buy domestic cottons. In this context, the Intensive Cotton Cultivation initiatives steered by cotton mills and ginning factories will help stabilize prices and ensure availability of desired quality required by our spinning mills. But, all this should be geared to urgently reduce the cost of production and increase India’s competitiveness.

23. In order to promote exports at prices which may provide remunerative returns to the farmers, export tariff, consistent with WTO provisions, may have to be provided to maintain the farmers' income and the overall cotton economy. Based on external demand and market situation, suitable level of export tariff may be fixed which may at least obviate the income depression due to low prices. The national system should, therefore, vigorously move to ensure export of the entire surplus produce. In order to circumvent the unrealistic non-tariff barriers imposed by the importing countries, mostly on SPS grounds, India should establish a credible SPS capacity to promote unhindered trade (Ref. Chapter VII of the Report).

B. Public Action:

B.1 Convergence and Synergy among Mini Missions:

24. It is strongly recommended that in order to revitalize the Cotton Technology Mission and to operate it in a true "Mission" mode, an eminent cotton professional be appointed as the overall full-time Mission Director. He/She will together with the four Mini Mission
Coordinators function as an apex management team with appropriate responsibility, authority and accountability to fully synergise the activities towards achieving the goal within the stipulated timeframe. The programme should be suitably redesigned involving a participatory approach and all the stakeholders, particularly the State Governments, internalizing the social engineering aspects with built-in mechanisms of monitoring, evaluation and dynamic adjustments.

B.2  **Enlarging the Role of Cotton Corporation of India (CCI):**
25. With the abolition of the quota system, CCI should play a greater role in insulating the farmers from the international price dips and in maximizing their profits when the prices go up. For this, it should be fully equipped to undertake market research and intelligence and position itself in time to meet the fluctuations. As the country’s cotton production increases, its capacity to procure, store and export cotton should be strengthened. In collaboration with APEDA and other concerned agencies, it should proactively advise the farmers on the quality and varieties of cotton to be grown.

B.3  **Reorienting Research Priorities and Technology Transfer Strategies:**

26. Notwithstanding the research priorities already identified under Mini Mission I, greater focus should be given to:

26.1 quality aspects, namely, fibre strength, better micronaire, length, high maturity, high extensibility, uniformity, low strength of attachment and short fibre content

26.2 development of broad-based Bt Cotton hybrids with desired fibre quality; use of MAS for pyramiding yield, quality and resistance genes, especially against abiotic stresses such as drought and creation of wide gene pools through inter specific hybridization; the undue delay in release of the transgenics should be avoided without compromising with transparency and biosecurity requirements

26.3 development of effective and stable bio-pesticides and biocontrol agents and to develop new IPM, IRM and INM techniques around the fast expanding Bt Hybrid system to
ensure greater sustainability, productivity and profitability.

27. The ongoing effort of the ICAR, Universities and private sector research systems should be assessed in terms of their degree of involvement both in terms of the human and financial resources deployed for the purpose and the intensity and the quality of the work. Additional resources and directed focus should be provided to the identified critical gaps through reallocation from the existing resources. Prima facie, no additional funds will be required but the need could be kept under continuing review. The Director, Central Cotton Research Institute, in close collaboration with Director, CIRCOT and other participating institutions, should be made responsible to follow up the work and regularly report the progress to the Mission Director.

28. Large-scale adoption of high yielding and superior quality arboreum varieties: Several high promising arboreum varieties, such as, PA-255, PA-402, DLSA-17, MDL-2463 have outperformed commonly grown hirsutum varieties by margins ranging from 35 to 50%, specially under water stress conditions. Besides yield, these varieties, particularly PA-255, possess excellent fibre quality which are comparable in all respects (length, fineness and micronaire, etc.) to LRA-5166, a leading hirsutum variety. By growing these excellent arboreum varieties, farmers had saved considerably on cost of cultivation (Rs.4900/ha. as against Rs.10,000 for hirsutum hybrids). The arboreum varieties were particularly outstanding under water stress conditions and in upper toposquence. Further, these arboreums have performed extremely well when intercropped with cereals, pulses, and oilseeds. Inspite of outstanding performance of new arboreum varieties, their commercial popularization has been extremely poor, depriving the farmers as well as the nation of a new opportunity of income growth as well as of environmental friendliness. It is strongly recommended that a focused extension and technology transfer programme involving all the stakeholders, particularly mills and the corporate sector, be vigorously pursued to saturate the cotton areas where the newly developed arboreum varieties hold distinct advantage over the hirsutum varieties or hybrids.

29. **Investing in the Soil Health:** Quantum jump in cotton yield can be obtained by addressing issues relating to the micronutrients status of the soils. Through pricing and policy instruments (input support) the nutrient balance should be corrected in the deficient soils. Zinc,
Boron and Sulphur deficiencies, in that order, were most common and the deficiency was greater in Maharashtra, Tamil Nadu, Haryana and Andhra Pradesh. Based on soil test, the imbalances should be corrected not only for recovering the potential yields but also for arresting further deterioration. Fertilizer industry should be encouraged to produce new and cost-effective fertilizer formulations (customized fertilizers) and participate in technology transfer. Any subsidy given on fertilizers must not ignore the vital role of and the urgency of promotion of the adequate use of critical micronutrients and a suitable measure should be put in place. The Ministry of Agriculture and the Fertiliser Industries should critically examine the suggestions and come up with a mutually acceptable action plan to restore and enhance the fertility and productivity of cotton fields to help promote INM. The TMC Director and Coordinator of MM-II should jointly chalk out detailed action plan with their counterparts in the deficient cotton-growing States and organize about 30,000 large scale demonstrations (atleast 1 ha. each) for mass impact and adoption.

30. Each farmer should be issued soil health card and trained to use the technology. Agriclinic and agro-business centers should be established strategically and rendered functional to undertake the necessary soil test. Despite all efforts and the declared policy and instructions to the banks, especially NABARD, to help establish agriclinics and agribusiness centers, so far hardly 200 units have been established during the past three years and these are operating with varying degrees of success. Serious mismatches exist in the attitude, mode of support and priorities of different partners, namely the entrepreneur, the bank, the farmer and the public sector. Thus, the move has so far not been as successful as initially conjectured. The situation has been analysed sporadically, but a more comprehensive analysis involving the different partners is called for which should come up with a new road map for improving the prospects of agriclinics and agro-business centers. There is a tendency to emphasise the business component and profit to the owner of the center at the cost of extension and knowledge services to the farmers.

31. **Enhancing Water Productivity and Saving Water and Soil Erosion:** Large tracts of cotton soils, particularly in the Central Zone, are shallow with hard pan at about 8 to 10" depth causing several interdependent soil, water and plant nutrition problems. Breaking the hard pan
will obviate the problems in many ways. Rain water is stored deep, down wherefrom it will not easily evaporate and is available to plants for a prolonged period and a much healthier and larger crop is produced. These reduce the need for irrigation particularly to deep rooted crops like cotton to as low as 20% of that normally required, and thus the water productivity will increase manifold. But, despite this knowledge and knowhow this water conservation technology has generally not been adapted in India. Chiseling (1 m interval) in rainfed areas would need high power prime movers such as 50 hp tractors because of larger draft requirements. Such tractors were not available until few years ago. Presently, both high power tractors and chisel plough are available to do the job. Traditionally, lack of high power tractors, research efforts, and extension efforts did not permit large-scale adoption of the chiseling operation. The cost of chiseling is estimated to be Rs 1000/ha. However, large scale demonstrations of about 100 ha. each in about 200 watersheds in 40 districts should be undertaken to assess the efficacy of the approach in terms of energy, economics and environment. Based on the results, a national plan should be prepared to benefit from the technology.

32. Other water harvesting, conservation and use techniques such as zero tillage, ridge-furrow planting, micro irrigation and plastic sheet mulching are used singly or conjointly. But these are restricted to limited sites and have not impacted cotton productivity in India. Toposequence based rain water management, rainwater harvesting and use, should be adopted by all rainfed cotton farmers as the technique is extremely useful in stabilizing and increasing the yield (on an average by 20%) on farmers’ field. Awareness campaign and initial financial support will prove stimulatory in popularizing the approach. Likewise, ridges and furrow system not only saves soil and water erosion but gives about 30% higher yield across all the toposequences and different cotton-based cropping systems. It also enhances nutrient use efficiency. An extensive drive and service support to promote these technologies should constitute a priority activity in all the rainfed cotton areas.

33. The high subsidy on micro irrigation equipments had encouraged the widespread sale of poor quality equipment and brought bad name to this highly effective technology. Transparency and good governance thus should underpin the popularization of such techniques. Strict monitoring and quality control of the supply of the subsidized hardwares of the micro irrigation
(drip and sprinkler) system should be ensured.

34. **Ensuring timely flow of adequate quantity of quality seed:** Despite the active involvement of the private sector and several seed production schemes of the public sector, both at national and provincial levels, the supply of quality certified seeds of the approved varieties is rather low and uncertain. Moreover, the multiplicity of the varieties grown further aggravates the situation. Therefore, first of all, the Government should urgently denotify the degraded varieties. The new Seed Act should be enacted and implemented at the earliest so that all the seed available in the market is certified and is distributed only through registered dealers and producers by authenticated systems so that, if needed, the defective link in the flow chain could be traced and corrected. The seed laws must be strictly adhered to and earnestly implemented. The defaulters should be punished to curb the distribution of spurious seeds.

35. The public and private sector together, specially the Cotton Corporation of India and Cotton Mills Federations together should identify the quantity of seed needed of the different varieties recommended for specific zones. The Basu Committee report on the retention of desirable verities and their zonal delineation should be urgently implemented. The Agri-clinic and Agri-business centers should be suitably strengthened to store and distribute quality seeds as a high priority. There should be a suitable arrangement also for either carrying over or disposing off the left over indented seed to protect the agribusiness centers from loss.

36. The National and State Seed Corporations should play a leading role in producing and distributing the quality seeds of open pollinated varieties. For this purpose, central and State seed farms, university farms and corporate sector farms should also be used. Keeping in view the excellent role played by women in the production of hybrid cotton seed, appropriate mechanisms of engendering cotton seed production by leasing out Government lands to women Self Help Groups (SHGs), such as SEWA, should be encouraged. Specialised women SHGs could be created for this purpose with adequate provision of training, skill development and access to financial resources. These specialised SHGs may also be charged with the responsibility of establishing and operating cotton seed banks (a separate note is being prepared on this aspect).
37. **National Movement to Adopt IPM:** A landmark in cotton IPM has been the validation of the cropping system based holistic community approach of IPM at village Ashta (1998-2001), a village in Nanded district, representative of over 2 million ha rainfed cotton in Central India. Large scale pilot demonstrations covering hundreds of villages in all the cotton-growing States have established the fact that the IPM approaches suiting to the regional requirement can drastically reduce the cost of production of this fibre in the country and it is possible to reduce the dependence on chemical pesticides to the tune of 60 percent and increase seed cotton yield by 24 percent. Yet, the technology is not being widely adopted. A national movement for cotton in IPM is called for. A three-year programme covering 5,400 villages, 540,000 ha, and costing Rs.600 crores (Rs 200 crores for one year) deserves priority implementation.

38. IPM approach also includes need-based and efficacious use of selected pesticides, while maintaining the emphasis on effective biopesticides and bioagents. Addition of eco-toxicological perspectives for the management of insect resistance to pesticides and insecticides would help obviate some of the shortcomings of the IPM approach. Further, the IPM and IRM strategies must be dynamically and synergistically evolved in light of the increasing introduction of Bt. Cotton and new insecticides.

39. Like the IPM approach, the results of the farmer participatory approaches in the IRM have been very encouraging and apparently farmer awareness is undergoing massive sweep as evident through the enormous reduction in the usage of pesticides in all the districts implementing the programme. Thus far 26 insecticide resistant monitoring centers have been established under the project and are expected to serve as insecticide resistance information centers to farmers throughout the season, so as to enable farmers take up properly guided decisions on the appropriate choice of insecticides. Currently, the per hectare operational cost (manpower, consumables, travel, etc) comes to about Rs.200. The programme focuses immensely on farmer education and does not provide any material inputs.

40. The IPM and IRM strategies and their proven efficacies and appeal notwithstanding, are unfortunately being pursued in parallel manner with no operational connect in the two separate
Mini-missions, MM-I and MM-II. Given the commonality of the two approaches, the disconnect between the two strategic programmes should be removed and the two programmes must be integrated under one and the same IPM umbrella, and there should be only one line of management and control for preparing, implementing and monitoring village level detailed microplans and their backward and forward linkages. All concerned stakeholders, the Department of Agriculture, ICAR, State Governments, SAUs, private sector, NGOs and farmers must forge the linkage and unify the efforts towards realizing quick and widespread impact.

41. The Report of the Joint Committee on Pesticide Residues in and Safety Standards for Soft Drinks, Fruit Juices and Beverages of the 13th Lok Sabha, under the Chairmanship of Shri Sharad Pawar, presently the Hon’ble Minister of Agriculture, contains some extremely valuable recommendations pertaining to IPM and IRM (paras 3.53 to 3.58), in addition to other important recommendations including those related to implementation of regulations and the punishment for non-compliance. The Report should be implemented soonest in our effort to save the farmers from mounting distresses from the use of spurious pesticides and ill-informed excessive use of prohibited insecticides.

**B.4. Byproduct Utilization:**

42. Byproducts of cotton cultivation and processing wastes should be subjected to value addition to enhance growers income and to develop rural employment and entrepreneurship. Technologies already developed such as utilization of cotton stalk for the manufacture of particle boards, for paper etc. need popularization, demonstration and adoption. Agro residues and byproducts need to be promoted as raw materials for industrial activity to fetch additional income to growers.

43. Scientific processing of cotton seed viz., delinting, dehulling and then crushing for oil to be promoted rather than seed to be directly crushed to oil as is being done right now. Value addition to each of these byproducts of cotton seed viz. linter, hulls, deoiled cake should be encouraged. Strategic linkages among private sector companies, Small Farmers’ Cotton Estates and NABARD should be promoted by the National Cotton Council.
C. Organising Small Farmers' Cotton Estates and Participatory Extension and Technology Transfer

44. Realising that the public sector extension and the service-providing machinery is almost defunct, and recognizing the successful experiences of certain public-private-farmer or private-farmer or farmer-farmer (SHGs) partnerships in transfer of technologies leading to the benefits of all the partners, new models of extension and service-providing mechanisms should be actively promoted and institutionalized. Some of the partnership initiatives such as the ICMF – CDRA project, the Appachi Foundation 60 SHGs, CCI-initiated Intensive Cotton Cultivation and the Vardhman Group’s participatory extension programme are bright spots deserving large-scale adoption.

45. Small Farmers' Cotton Estates through “Group Farming”, linking production and consumption through effective partnership of farmers, service and knowledge providers, formal credit providers viz. NABARD, input providers and marketing and product distribution agencies both in public and private sectors should be established. The approach aims to (i) make available cotton of desired quantity and quality to the user industry and an assured market to the producer, (ii) improve productivity and quality of cotton by providing the farmer with authentic inputs such as seed, fertilizers, pesticides and know how, and (iii) bring change from subsistence agriculture to commercial agriculture and thereby increase the profitability of the farmer.

46. Active participation of the cotton mills, NGOs and related sectors can further be promoted and institutionalized by providing incentives to them. Keeping in mind the high impact of the Scheme on the livelihood security of the cotton growers and the competitive advantage to the industry under the post-WTO environment, the Government should provide the needed support. To begin with, the State Governments should waive the market cess and sales tax. Failing that, the Central Government should provide subsidy to the extent of 50% of the cost of market cess and sales tax for a period of five years. Further, the Government of India may bear the cost of supervision of the programme by agricultural experts and also provide cost of
scouts for monitoring the crop under the MM-III. Detailed financial implications of these provisions should be worked out.

47. Recognising the importance of MM-II in enhancing the productivity and competitiveness through efficient transfer of technologies, and appreciating the role that the private enterprises and NGOs can play in supplementing the public sector effort in rapid diffusion and adoption of appropriate technologies, the funds for extension work under MM-II should flow also to the proven nongovernmental partners under analogous terms and conditions. Such efforts should first be intensified in the high yield-gap and low-yield cotton districts, selected preferably from the list of districts identified by the Planning Commission. This decision should be made widely known and private enterprises, especially those related with cotton industry, and NGOs should be invited to participate in the programme.

48. To begin with, 100 Small Farmers' Cotton Estates, each covering about 1000 ha., may be launched by the National Cotton Council in close collaboration with the TMC, ICMF, NABARD and CCI. These Cotton Estates will function on the principle of decentralized production by small farmers and supported by key centralized services at the production and post-harvest phases. Each EState can be supported by an Agri-clinic and Agri-business Centre operated by Farm Graduates. The Small Farmers’ Cotton Estates can each host a Rural Knowledge Centre based on modern information communication technology (ICT).

49. Credit, insurance, marketing may all be included in the EState. The design of the Small Farmers’ Cotton Estates should be such that it represents a win-win situation for all participatory farmers. Production – processing – marketing can be dealt with in an integrated manner.

50. Based on the initial experience and the response of the partners, it is proposed to cover within the next three years about 5000 villages throughout the cotton growing States in the country, but with greater concentration in Maharashtra, Gujarat, Andhra Pradesh and Madhya Pradesh, covering an area of about 1 million hectares with an yield advantage of about 50 percent above the present level. This yield gain is estimated to provide additional net income of Rs 5,000 per ha. to nearly 500,000 farmers, valued at Rs 500 crore.
51. **Credit, insurance and institutional support:** As mentioned earlier, since cotton production is highly risk prone and is largely in the domain of small and resource-poor farmers whose risk taking capacity is extremely low, the importance of smooth and timely access to formal credit and insurance can hardly be over-emphasised. The recommendations made in Chapter-II to address this issue is equally applicable to the cotton farmers and cotton productivity.

**Financial Resources**

52. Factor oriented interventions such as micro-nutrients, quality seeds, bioagents, biopesticides, integrating with system oriented demonstrations, namely, IPM, IRM and INM need to be provided for intensifying these demonstrations in resource poor farmers’ fields in the low-yield cotton districts. Development of Bt. and other biosafe new seeds, new biocontrol agents, popularization of new arboresum seeds especially in drought prone areas and establishment of Small Cotton Holder Estates are other priority critical interventions for increasing productivity and competitiveness. The TMC and ICAR should provide part of the funds needed through reordering of priorities. An additional sum of Rs 250 crore may be provided in the budget for 2005-06 to launch an integrated technology transfer and development programme geared especially to meet the needs of the small farmers and to capture the opportunity arising from the ending of the multifibre agreement.
Towards a Biosecure Trade: Urgent Steps Needed

1. Producer-centred assured and remunerative marketing holds the key to ensuring sustained agricultural progress. Enhanced trade in farm commodities is essential for promoting agrarian and rural prosperity. Trade also generates downstream non-farm employment opportunities. In its next report, the National Commission on Farmers will be presenting recommendations for developing a dynamic farmer-centric Indian Common Market. A few suggestions for safeguarding and expanding international trade in agricultural products are given here.

2. Our facilities for sanitary and phytosanitary measures (SPS) are inadequate. According to Financial Express (India) 16 Feb, 2004, several consignments of Indian farm exports were rejected on grounds of mycotoxin, salmonella, pesticide residues etc. during last two years (Annexure I). The situation is likely to get serious in the coming years since health safety standards as presented by Codex Alimentarius are getting increasingly stringent and the goal posts in developed countries have been shifting fast. Food safety standards will become the most important non-tariff barrier. Therefore, we must not lose any further time in launching a quality and food safety literacy movement in villages. At the same time, our SPS infrastructure should be vastly strengthened. Suggestions are given in this Chapter on urgent steps and investment needed.

3. We should also strengthen our quarantine facilities, since according to National Bureau of Plant Genetic Resources (NBPGR), several invasive alien species have been introduced into the country along with grain seed and planting material imports. These introduced pests include bunchy top of banana, potato wart, sunflower downy mildew, coffee pod borer, apple San. Jose scale, Biotype B of white fly and invasive weeds like Lantana camara and Phalaris minor. Such
invasive alien species will further threaten our agriculture, including poultry and dairying. The Asian Flu disease of chicken in southeast Asia is a case in point.

4. In the wake of implementation of WTO-SPS Agreement we are faced with the following challenges:

4.1 Designate a single Central Government authority as responsible for implementation of SPS measures.
4.2 Review and updating of legislation and regulations related to SPS to give effect to international agreement and establishing a nodal point for enquiries and information exchange
4.3 Establishment of national standards on SPS measures in line with international standards
4.4 Establishing a notification procedure
4.5 Undertake pest risk analysis and identify and maintain pest-free areas for plants and animals as per international standards and safety assessment for food
4.6 Scientific justification of high level protection in the absence of pest risk assessment
4.7 Recognition of equivalence of specific measures through bilateral or multilateral agreements
4.8 Identifying researchable issues and strengthening back-up research
4.9 Capacity building in terms of infrastructure and expertise
4.10 Awareness building and catalyzing attitude change
4.11 Develop functional public-private-NGO partnerships

The Road Ahead:

5. In view of the urgency of the steps needed both to safeguard our agricultural exports and to capture new markets, the following steps are suggested.
A. Policy Actions:

6. **Food Safety Council of India:** It is suggested to establish a Food Safety Council of India chaired by the Union Minister for Food and Agriculture with the Union Commerce Minister as co-Chairman. The Food Safety Council of India should have as members, representatives of farm and fisher women and men, particularly from States with a large volume of agricultural exports. The producers’ representatives should cover all aspects of crops and animal husbandry and fisheries.

B. Public Actions:

7. **Upgrading the Quarantine Stations:** The five major quarantine stations at New Delhi, Mumbai, Kolkata, Chennai and Amritsar have been modernized with sophisticated equipments and Post Entry Quarantine facilities under a UNDP project. However, there are other 24 plant quarantine stations for the upgrading of which an initial effort has been made for need assessment in terms of laboratory and green house facilities required under an FAO-TCP project recently. The 24 stations were classified into three broad categories in the said project based on nature and volume of material received in each of the stations. The output of the project can be a starting point to initiate upgrading of these stations. It may however be noted that apart from equipping these stations with modern instruments and facilities, the means of communication (telephone, fax, email, vehicle) need special attention for efficient functioning of these stations.

8. **Development of National Standards on Sanitary and Phytosanitary Measures:** The establishment of national standards on phytosanitary measures in line with international standards is of critical concern to meet the stiff challenges under the international agreements. There are 21 such international standards developed as on today. For this purpose, the Food Safety Council may constitute a National Committee on SPS Standards and suitable standard setting procedure need to be developed. The National Committee may assist in developing the standards and the draft standards may be circulated among the functionaries for their comments and the finalized standards may be duly approved and signed for issue to concerned Central/State level functionaries for adaptation.
9. **Survey and Surveillance Programmes:** So far no systematic efforts are being made for survey and surveillance of endemic pests, of new and emerging pests and of the exotic pests which have been introduced and are being spread. An effective integrated pest surveillance system and organization devoted to performing field inspection and pest survey activities for the detection, delimitation or monitoring of established pests as well as system and organization devoted to the detection of new pests needs be introduced. Specific systems may be required for identification, establishment and maintenance of pest-free areas as per the international standards. Similarly, systematically designed survey, surveillance and monitoring studies for the toxin incidence in food and agricultural commodities are required to identify less risk-prone areas for export and domestic use. For this, need-based additional support is needed to strengthen containment facilities, pest risk analysis capacity, pest diagnostic laboratories, residue and toxic laboratory, referral laboratories, emergency control and treatment facilities and accreditation laboratories.

10. **Generating Awareness abroad and Linkages with National and International Programmes:** In order to have complete understanding of the SPS measures of our target markets, there is a need to have direct technical contact with the concerned authorities in those countries. This could be achieved if the country posts a technically qualified Agricultural Attache at our diplomatic offices in the countries of interest. ICT must be effectively used to enhance awareness abroad on the steps taken in India to ensure the highest standard regarding food safety and biosecurity.

11. At present the staff of Directorate of Plant Protection, Quarantine and Storage (DPPQS) works largely in isolation and are not taking benefit of the various research organizations of ICAR and State Agricultural Universities for detection and identification of pests and for the control strategies. There is a need for an active linkage between All India Coordinated Research Projects (AICRPs) and the activities of the DPPQS in order to have comprehensive survey and surveillance programmes. There is an urgent need to develop a network system of information through the following means: (i) linkage with WTO, Cotton Advisory Council (CAC), IOE, International Plant Protection Convention (IPPC), FAO, WHO, International Standards
Organization (ISO) and related organizations, (ii) coordination mechanism involving planning and network system, (iii) dissemination of information on standards and code of practices and (iv) forging networks to implement contract farming.

12. **Researchable Issues**: The diverse areas requiring research input for preparing an authentic and accurate Pest Risk Analysis (PRA) such as pest status information to establish phytosanitary regulations, risk identification through development of more sophisticated bioassay, chemical or genetic analysis based on molecular or serological tests apart from morphological characteristics, evaluation of introduction/establishment and spread potential on the basis of risk of entry and establishment of the target pests and epidemiological data on a potential pest correlated with meteorological data, economic impact data in the form of national and global pest database depending upon the information on pathogenicity, etiology and control. For identifying PFAs authentic, extensive survey and surveillance is a must for authentic mapping of endemic pests present in localized pockets. Also, research is needed on suitable pest risk management practices to increase export potential of commodities/material in areas where the pest is within tolerance limits.

13. Research needs to be carried out to develop detection techniques for diagnosis of destructive pests especially to test samples of bulk consignments in batches. Alternative salvaging techniques to reduce the dependence on chemicals for control of pests and use of physical treatments like heat/cold, physico-chemical or ionizing radiations as alternatives to fumigation needs to be worked out.

14. Research on toxins with special reference to mycotoxins such as tolerance limits for the aflatoxins based on the regional diets and mean daily estimated intake of aflatoxins and its role as a immunosuppressant and carcinogen is needed.

15. **Human Resource Development - Launching a Trade Literacy Movement**: To meet requirements and challenges of SPS Agreement, the country needs specially trained manpower
as under the Agreement, PRA, a mandatory requirement to be carried out by all importing countries requires input from a team of scientists of all plant and animal protection scientists, database managers, weather forecasters, environment experts and agricultural economists. Research scientists who could strengthen pest identification through modern molecular techniques and make the imports pest free through efficient salvaging treatments/ techniques need to be internationally trained.

16. The database on prevailing pests in the country needs to be updated through not only literature survey but also survey and surveillance of land under agriculture, forests and wild fauna. This being a huge task requires networking and suitably training of plant and animal protection scientists of ICAR and SAU within the country. Such accumulated data on pest distribution can also be exploited to meet the requirement under the Agreement and to boost up our exports of agricultural commodities from certified and notified pest free areas. Trained manpower is also required for maintaining pest free areas as pest free through suitable phytosanitary measures.

17. With more and more speculated exchange of transgenics in plants, animals and fisheries during the coming years, disciplines like biosafety needs to be upgraded to international levels. For this, the biotechnology laboratories need to be equipped with suitable manpower and equipments to detect transgenes and terminator genes in the suspected agricultural produce (in bulk) and processed products. Trained manpower is required to study and compile information on adverse effects of the transgenics on environment, human beings, biodiversity, wild flora and fauna.

18. At present there are a large number of cases of dispute related to technical aspects of import and export of agricultural products that are lying pending for settlement of both developing as well as developed country members before the Dispute Settlement Committee of WTO. Looking at the number of such cases being addressed, there is a need for developing legal expertise in this field.
C. Quality Literacy Programme: Sensitization and Awareness Building:

19. Awareness about SPS measures has to percolate down to the producer and processor levels so that the significance of these issues in enhanced global trade could be highlighted. Such an efforts needs development of tailor-made training programmes for different clientele groups and targeting the field-level awareness-building. ‘Hands on’ training should be imparted to selected clientele groups who can help in horizontal dissemination of technology especially for mycotoxin estimation, pest-diagnosis etc. ICT based Village knowledge centres must play a major role in creating the awareness among producers and consumers alike in rural areas (Ref Chapter VIII). The use of existing technical systems such as the Virtual Academy for Semi-Arid Tropics (VASAT) could be used as a platform for quick dissemination of Good Agricultural Practices (GAPs) and Good Manufacturing Practices (GMPs) for different production systems.

20. The State governments need to be sensitized and supported to develop mechanisms for ensuring compliance to legislative measures and SPS standards through local stakeholders. They need to ensure funding and establishment of facilities such as post-entry quarantine glasshouses, well-equipped laboratories for diagnostics and determination of residual toxicities and should encourage human resource development in the relevant areas. All stakeholders must be sensitized of the need for adherence to biosecurity provisions.

Financial Resources

21. In order to meet our SPS commitments, the country should urgently strengthen the operation system at all strategic points, diagnostic surveillance and accreditation system, science-based pest risk assessment and management, audit and quality control system and information and literacy campaign. To attain these outputs, additional investments are needed for creating infrastructure missing at strategic sites, for improving laboratory facilities, for augmenting trained human resources, for undertaking emergency actions and for creating databases. An additional sum of Rs. 100 crore is required for the next two years to achieve the goal. An allocation of Rs. 60 crore is recommended during 2005-06.

Ecologically sound agriculture is knowledge intensive. Farm women and men need dynamic information relating to meteorological, management and marketing factors as related to crops and animal husbandry, fisheries, agro-forestry and agro-processing. The new approach to productivity improvement and employment generation is also information and knowledge intensive. In the context of globalization of trade, there is need for launching a genetic (i.e. relating to genetically modified farm products), legal (i.e. IPR and Farmers’ and Breeders’ Rights), quality (i.e. sanitary and phytosanitary measures and codex alimentarius standards), and trade (i.e. prices in home and external markets) literacy movement. There is presently a disconnect between what farm families need by way of generic and dynamic information and what the conventional extension agencies are able to provide.

It is also important to address the need for demand driven and value added information which is time and location specific. There is also need for knowledge transfers between and across rural communities, scientists, educators, administrators, healthcare providers, technology enablers on local agro-ecological and socio-cultural conditions of each village, and also relating to various farming methods and techniques. This can be effectively done through a network of Rural Knowledge Centres (RKCs) across the country. The principles of social inclusion, gender equity, reaching remote areas and remedying regional imbalances should be inbuilt prerequisites in the design of the RKCs. With a system of rural Knowledge Centres in place, families in rain-fed and dryland areas can access their information needs with facilitation from a district level consortium, and can raise their queries. This arrangement can be used in skill building at the local level and information empowerment with the help of contemporary Information and Communication Technology (ICT) methods, using the practice of just-in-time instruction.

2. Apart from information related to farming, rural women and men urgently need access to healthcare information. Increased health expenditure is an important cause of farmers’ indebtedness, leading occasionally to suicides. Information on the health status of
livestock and poultry, on-farm and off-farm livelihoods and market-led entrepreneurship opportunities for the poor and the marginalised in rural India need attention. There is also need for promoting functional literacy among the adult illiterate and making learning joyful for the young through interactive pedagogic methodologies.

3. Fortunately, the country is now in a position to take the benefits of the internet, community radio, cable TV and vernacular press to all the 600,000 villages within the next few years. A National Alliance for MISSION 2007: Every Village a Knowledge Centre has been formed to mobilize the power of partnership among the public and private sectors, academia, mass media and civil society organizations. Article 243 G of Schedule 11 of the Constitution 73rd Amendment Act 1992 on Panchayats, lists agriculture including agricultural education, animal husbandry, fisheries, forestry, education, technical training and vocational education, adult and non-formal education among the responsibilities of the Panchayats. The Rural Knowledge Centres can be located either in Panchayat buildings or rural schools or Study Centres of Open Universities, so that there is social inclusion in access. These Rural / Village Knowledge Centres (VKCs) can be run by self-help groups (SHGs), after the members of the SHGs are thoroughly trained. NABARD could develop a special scheme for supporting ICT SHGs. The community owned VKC will connect to the Internet and use a variety of local methods (e.g. notice boards, loud speakers, local daily etc.) for dissemination. The VKC will provide access to key local information on entitlements, governance and infrastructure, while supporting access to dynamic information on weather, markets and online public services. The centre will also be a retail outlet for a host of online learning, skill building, and training services that are fast coming up in the country, providing information on employment opportunities, and will link to new and emerging extension services.

4. The public policy support and public investment needed for this initiative are indicated in this chapter. We should lose no further time in improving our agricultural efficiency and competitiveness through rural knowledge connectivity. Hence, the recommendations made herein may be examined speedily and appropriate provision made in the Union Budget for 2005-06.

It is important to emphasize that Connectivity, Content, Capacity building and Management should receive concurrent attention. The institutions that can undertake these tasks should be identified and their roles and responsibilities clearly defined. An effective
combination of these enabling agents will help us achieve improved quality of life and sustainable rural livelihoods for millions in rural India, as envisaged under the Common Minimum Programme of the Government.

5. Immediate Thrust Areas:

A. Universal Service Opportunity

ICT based growth of the service sector and concurrent economic growth have been impressive but largely urban centred. 70% of India is rural and dependent on agriculture and allied activities. But rural India is yet to be brought to the forefront of ICT-led knowledge economy. This segment living in rural and semi-urban areas is however the nation’s core strength and would determine the demand and supply base for a range of goods and services. Consumer goods companies, automobile manufacturers, TV and radio producers have proven the strength of this segment by expanding into rural areas. Mobile telephony has followed this trend and proved that the rural markets have a great opportunity to take advantage of ICT tools if the prices are right.

The Universal Service Obligation (USO) Fund offers opportunity to connect the unconnected to the national mainstream by broadband and internet telephony. The goal of reaching all the 600,000 villages can be achieved if the 30,000 BSNL exchanges are extended to rural areas through wireless technologies. Wireless technologies have the potential to develop rural networks on IP to provide unlimited bandwidth on demand and at minimal expenditure. The USO Fund policy must encourage higher bandwidth connections and support developing more innovative bandwidth price fixation formulae. Bandwidth prices may be reduced by reducing International Private Leased Circuit (IPLC) half-circuit prices for international connectivity and domestic lease lines. Telecom Regulatory Authority of India (TRAI) has completed consultations with regard to domestic lease line ceiling tariff as well as IPLC tariff. Their recommendations should address the unused national resource and recognise the need for providing incentives for connectivity projects to reach out to rural areas.

TRAI has recently presented consultation papers on Spectrum Policy, Pricing of IPLC Half-circuit, Domestic Leased Lines, Unified Licensing Policy, and on Rural Connectivity.
B. Need for Rural ICT Policy

A rural-friendly ICT policy that recognises the government’s fibre network as a national asset and offers concession to those who extend the network to rural India will certainly prove to be a big boost to the rural GDP in the coming years. Out of the 16 terabits of international connectivity, only 0.35 terabits have been lit and less than 0.20 terabits are being used. Most of the corporate and government fibre network combined is now dark. Fibre optic network of Bharat Sanchar Nigam Limited’s (BSNL) 30,000 exchanges covers all the 6,000 blocks of India. If only each exchange is extended to 20 villages, the entire country will be covered, and a nationwide e-connectivity network will be a ground reality.

Complementing the new ICT revolution, it is important for the government to recognise the need for the establishment of community radio stations at both village and block levels that have the potential to reach out to rural communities. The Supreme Court’s ruling in 1995 stipulates that airwaves are public property. The government has recognised the technical feasibility of establishing 4000 community radio stations at no cost. These establishments will extend the government’s audiovisual and publicity efforts on various entitlements and programmes and information on technical, socio-economic and health related issues, while empowering the rural community to communicate and develop structures for a knowledge-intensive rural production system.

Community radio, locally owned and managed within a limited range, would offer an inclusive medium to communities, literate and illiterate, men and women, rich and poor, to access locally relevant knowledge, raise concerns and participate in decision making. However, Government policy on Community Radio has opened up licensing only to educational institutions. This excludes Community Radio as an option for the vast majority of village communities. There is an urgent need to review the existing policy on Community radio with a view to making it more inclusive. To make this a viable option for local communities there is also a need to revisit the licensing and spectrum fee structures. We should not deny ourselves the power of the community radio in maximising the reach of the internet.

The recent announcement to declare 90% concession on domestic leased lines used for e-Governance service, needs to be extended to the entire country. While this decision will prove useful in reaching government’s e-Governance services to rural areas, the same
network will help content providers to provide information services and useful ICT-enabled applications to farming families.

The emergence of Rural Knowledge Centres and info-kiosk movement in our country, promoted by NGOs and corporate sector, have demonstrated that the local panchayats and self-help groups can take advantage of appropriate information and communication technologies and with this facility, they can easily access the scientific and technical knowledge they need, to solve local problems with greater precision.

6. Rural Knowledge Centres in 600,000 villages in India

The aim of Mission 2007: Every Village a Knowledge Centre is to trigger a knowledge revolution in rural India by setting up ICT based village Knowledge Centres (VKC) in each of the 600,000 villages in the country by the 60th anniversary of India’s independence. Success of the initiative requires cooperative mobilisation of resources by concerned departments of government, private sector organisations and civil society groups.

The exercise can commence on a priority basis in 2005-2006 in the 150 districts identified by the Planning Commission for the Rural Employment Guarantee Programme. To start with, 20,000 tele-centres can be set up to cater to 100,000 villages in the 150 districts, with each centre servicing 5 villages. A business plan for the budgetary support required is attached as Annexure I.

7. Rural Virtual Academicians – the one million Change Agents

It is important that the knowledge centre in each of 600,000 villages is owned and run by local community members thereby creating a stake in ownership and management. Atleast one woman and one man can be selected from each village as Fellows of the National Virtual Academy (NVA). (The M S Swaminathan Research Foundation with support from the Tata Trusts has established the Jamsetji Tata National Virtual Academy for Rural Prosperity). There is need to select one million Fellows of NVA by 15th August 2007 - the sixtieth anniversary of our independence, through a peer review process. They will serve as the torchbearers of the Knowledge Revolution in Rural India. Several agencies have agreed to support the training of this cadre. These rural academicians affiliated to Panchayati Raj institutions, will be the information providers for the local community and will help to reach the unreached and voice the voiceless.
Government policy must encourage outsourcing of government functions such as digitisation of land records, data entry operations, collation of local data and local resource mapping to the ICT-SHGs and community interest groups that run the Knowledge Centres. This will encourage the Panchayati Raj Institutions and local government structures to utilise these Knowledge Centres for providing accountable and transparent services to citizens. Panchayats can effectively use the VKC as a service provider and revenue earner. Outsourcing from urban to rural India will be a powerful method of bridging the rural-urban digital divide. The active participation of elected women and men members of local bodies is crucial for the success of this movement.

In recent years, the rapid maturity of self-help groups in many parts of India, and the evolution of distance education from postal tuition into IT-mediated learning provide unprecedented opportunities to extend information support to the rural families. SHGs have been linked to the village Knowledge Centres successfully in TN, AP and Pondicherry for micro-enterprise training and marketing of products, while in Maharashtra, considerable progress has been achieved in linking rural IT initiatives to non-formal, non-degree learning.

8. Support systems for rural knowledge revolution - Recognition of Rural Service Providers and their role in creating and sustaining rural micro-enterprises

It is important for the government to support pockets of excellence in content streams and offer assistance to those who handhold rural academicians and the Rural Service Providers (RSPs). The community groups that manage the VKC have to be supported by a range of RSPs. These RSPs could include those who extend the national asset of BSNL’s fibre network and government’s eGovernance programme into rural areas; and those who offer content services to rural people on education, health, and livelihood opportunities. Appropriate incentives to these RSPs would enable employment growth in the form of rural information entrepreneurs. A low or no interest rate lending to rural entrepreneurs, ICT-SHGs and Community Interest Groups with support from Panchayati Raj Institutions can spearhead a rural knowledge movement. Credit institutions such as NABARD and SBI are increasingly interested in rural lending that is founded on knowledge and sound information, and authentication of data; information and training by the established institutions will strengthen the capacity of rural families in credit-seeking efforts. A venture capital fund can also be established to support RSPs and VKCs.
The RSPs are vital for creating sustainable rural micro-enterprises in the area of agriculture, food processing, animal husbandry, fisheries, sericulture, handicrafts, rural industry and even in IT-based services (which rural India could provide to urban areas). The RSPs are all the more vital in developing a rural to urban e-Commerce service network. As a part of the government’s eGovernance rollout, ICT entrepreneurship workshops could be initiated.

The viability, sustainability and scalability of the rural knowledge revolution movement will ultimately depend upon the relevance of ICT to the lives of rural families. Private sector industry can play a major role in linking rural products with markets. This will help in mitigating farmers' distress. The rural economy can flourish if ICTs are leveraged to create new livelihood opportunities in the areas indicated through training and capacity building. Private sector and civil society organisations should be encouraged to develop ICT-based supply-chain management systems to sell rural products.

The support system for a rural knowledge revolution should be complemented, by establishing a National Digital Gateway for Rural Livelihood Security. There is need for investment in creating databases relevant to rural needs. For example, a decade ago, a National Agricultural Drought Assessment and Monitoring System was set up under the National Remote Sensing Agency (NRSA) to facilitate improved decision making by farmers in the kharif and rabi seasons. The potential of this system needs to be harnessed for giving proactive advice to farm families on land and water use planning. The architecture of such a gateway should be based on currently available digital content from diverse agencies, ranging from the ICAR to the NRSA and ICRISAT, with a focus on improving livelihood security in rural India. Every participant agency should be encouraged to create well-adapted and annotated digital content (maps, numeric data or documents etc.) in a manner accessible to non-specialists. About 20 such web servers can be linked by a gateway computing platform through which a user can access the information.

10. Farmers’ Distress Call Centres

Livelihood opportunities in rural areas can be safeguarded by setting up Farmers’ Distress Call Centres in every State of the country. This is especially important in the context of farmers’ suicides. These distress centres will mediate on behalf of the farmers and
enable the experts and those who can offer solutions to the problems faced by the farmers. Application of ICT tools such as telephone and voice mail would enable farmers to obtain timely advice.

11. The role of Civil Society in eGovernance Programme

Civil society groups can provide inputs for the government’s eGovernance policies. Such groups can advise the government on appropriate methods of automating government processes and offering ICT-enabled services and applications for rural communities. Such groups can also ensure sponsoring civil society and professional organisations involved in building capacity among the ICT-SHGs and community interest groups in rural areas.

There are four major components to Mission 2007. These are:

(a) **Connectivity**: As already mentioned, India is in the fortunate position of being able to connect all the 600,000 villages speedily. BSNL and all the other agencies working on connectivity, including educational institutions like IIT, Chennai, should join together in fostering the rural connectivity movement.

(b) **Content**: This has to be location specific and need based. Education, health, water, weather, market and technological empowerment should all receive priority attention. A wide range of agencies will have to be involved for creation of relevant content. A blend of non-formal training approaches, content creation in a virtual mode and its use at Village Knowledge Centre is necessary for making a mass impact. A multi-institutional and multi-disciplinary **Content Consortium** can be formed in every district.

(c) **Capacity Building**: This is a very important component of the Action Plan and again a District level **Capacity Building Consortium** can help to organise capacity building programmes using the pedagogic methodology of learning by doing. The Academicians of the Jamsetji Tata National Virtual Academy can become master trainers.

(d) **Care and Management**: The care of the equipment and management of the Knowledge Centre can be undertaken by trained ICT-SHGs linked to Panchayats.

In this manner, an integrated self-sustaining and self-replicating system of Village Knowledge Centres can be built up. These Centres will be powerful instruments for making the Right to Information (at the correct time and place) a reality.

Wireless Connectivity

Two phones: Rs. 20,000

**Total: Rs. 1,20,000**

(Government should facilitate providing connectivity through BSNL, ISRO and MIT).

Basic Cost of setting up a Knowledge Centre is Rs.120,000

**Additional Cost**

Power Supply through Generator: Rs.30,000

or

Solar Power: Rs.1,25,000 (possible subsidy from Ministry of Non-Conventional Energy Sources)

Assuming use of generator, **Rs.1,50,000** (Rs.1,20,000 + Rs.30,000) is the **basic cost** for setting up the infrastructure of a VKC.

Minimum Running Cost

Salaries for two - Rs. 6000/- per month = Rs.72,000 per annum

Telephone, Maintenance, Administration @ Rs.2500 per month = Rs.30,000 per annum

Total: Rs.72,000 + Rs.30,000 = Rs.102,000 per annum

**Basic Cost + Running Cost** = Rs.252,000 (Rs.1,50,000 + Rs.1,02,000) in the first year, say **Rs.2,50,000**
Therefore Cost of Setting up and operating a VKC will be Rs.250,000 in the first year.

From the second year there will only be the recurrent cost of Rs.1,00,000 per year.

A provision may be made under the USO Fund or Ministry of Panchayati Raj for setting up 20,000 VKCs in Panchayats in the 150 districts, each VKC catering to a cluster of five villages (population served 10,000 – 12,000).

This will require a one-time allocation of **Rs.500 crore** in the first year. Subsequently the running cost may be met on a tapering basis over a four-year period from the second year onwards, with 20% of the cost being self generated cumulatively in each successive year and the centre being fully self-supporting from the 6th year onwards.

The Centres will be powerful instrument for making the right to information (at the correct time and place) a reality. Content Creation and Capacity building of trainers and users will be additional costs over and above this basic cost. This will have to be met by a pool of agencies (Government, Private Sector, Civil Society Groups) in the initial years and may be coordinated by the District Level Content and Capacity Building Consortia.

CHAPTER IX

FOOD AND NUTRITION SECURITY

The terms of reference to the National Commission on Farmers call upon the Commission to work out a comprehensive medium-term strategy for food and nutrition security in the country. Based on widespread consultations and on the findings reported in the Food Insecurity Atlases of Rural and Urban India prepared by the M.S.Swaminathan Research Foundation and the U.N.World Food Programme, the following 7-point Action Plan is recommended for inclusion in the Union Budget for 2005-06, under the title “Mission 2007: A Nutrition Secure India”. The Tenth Plan calls for a paradigm shift from food security at the national level to nutrition security at the level of every child, woman and man. NCF suggests the following definition of Nutrition Security: “to ensure physical, economic, social and environmental access to balanced diet and clean drinking water for all and for ever”.

Physical access is a function of production, while economic access is a function of purchasing power based on sustainable livelihood opportunities. Social access calls for gender equity in access to food, while environmental access involves the impact of drought and floods on food availability as well as sanitation and environmental hygiene. Balanced diet demands concurrent attention to protein calorie under-nutrition and to hidden hunger caused by the deficiency of micronutrients like iron, zinc, iodine and Vitamin A in the diet. Adequate nutrition and education are two basic requirements for a healthy and productive life. Malnutrition leads to significant macroeconomic costs. It has been estimated that malnutrition is reducing national GDP by more than 3 percent. Maternal and foetal undernutrition resulting in the birth of babies with low birth weight (2.2 Kgs or below) represents the cruelest form of inequity, since it denies a child even at birth an opportunity for the full expression of the child’s innate genetic potential for physical and mental development. According to the surveys of the National Nutrition Monitoring Bureau, at least 200 million children, women and men suffer from protein-calorie malnutrition. The extent of malnutrition varies among and within States, but is
higher in rural India as well as among women and girl children. There is a close correlation between hunger and poverty and that is why the eradication of hunger and poverty occupies the first place among the U.N. Millennium Development Goals.

**Nutrition Security Action Plan**

a) **Adopt a life cycle approach in the delivery of Nutrition Safety-net programmes under the aegis of Panchayati Raj institutions.**

The principal safety-net programmes currently in operation are the following.

- The targeted PDS designed to provide subsidized foodgrains to all households below the poverty line.

- The ICDS aimed at supplementary nutrition, growth monitoring, nutritional education for pre-school children and expectant/nursing mothers.

- The National Programme of Nutritional Support to Primary Education.

- The National Food for Work Programme in 150 rain-fed districts and the Rural Employment Guarantee Scheme aimed at providing 100 days of employment per household per year.

- The Annapurna Scheme aimed at providing relief for the aged poor (10 Kg. of foodgrains per month per person free of cost)

- The Antyodaya Anna Yojana aimed at the poorest of the poor.

There are also special schemes to promote breast feeding and complementary feeding in the case of infants and to address micronutrient deficiencies like iron, iodine and Vitamin A. **Kishori Shakti Yojana** is a special intervention designed for adolescent girls in the age group 11-18 years using the ICDS infrastructure. A Nutrition Monitoring, Mapping and Surveillance System has been established through ICDS. **A National Nutrition Mission** has been initiated under the Department of Women and Child Development of the Ministry of Human Resource Development.
In spite of all these initiatives, endemic hunger arising from poverty is widespread and seems to be on the rise. The incidence of Low Birth Weight babies is also very high. Hence, there is need to streamline the delivery mechanisms by introducing a horizontal dimension to the numerous vertically structured programmes. The whole life cycle approach will cover the vulnerable sections from birth to death in a holistic manner. Such an integrated nutrition delivery system is best established under the Panchayati Raj institutions. Transaction costs can be reduced by adopting a whole life cycle approach.

b) Fill gaps in on-going programmes.

It is widely recognized that young infants in the age group 0-2 are not reached through ICDS. Yet, this is the stage when brain development is proceeding at a fast pace. Additional support will have to be provided to pregnant and nursing mothers to ensure both adequate foetal nutrition and later, infant nutrition. Another gap which needs to be filled up is the provision of nutrition support to HIV/AIDS-Tuberculosis infected women and men in rural areas. A drug based approach alone is not adequate to help farmers and farm labour regain the necessary strength for working efficiently on the farms. It is suggested that during 2005-06, the following provisions may be made to fill these critical gaps:

- Supplementary nutrition for adolescent girls, pregnant women and infants (0 to 2 years) – 250,000 tons of foodgrains.
- Nutrition support for HIV/AIDS-Tuberculosis affected persons in rural areas – 100,000 tons of foodgrains.

c) Provide Household Entitlement Cards to all eligible persons.

Information empowerment is vital for ensuring that entitlements reach the poor. Access to entitlements can be improved by issuing to all eligible families Household Entitlement Cards which provide precise information on their entitlements to social and nutritional safety net programmes and on methods of accessing them.
d) Introduce an Integrated Food Guarantee Programme, combining the features of the National Rural Employment and Food for Work schemes. Such a programme should be gender sensitive and should enlarge the scope of work in the case of women to include items like organizing and managing crèches and child care centres for working mothers, assisting the Anganwadi Centres in implementing the immunization, health and supplementary nutrition programmes, the management of Food and Fodder Banks, etc. Using foodgrains as cash has the additional advantage of stimulating increased production, since farmers will produce more if the consumption capacity goes up.

e) Promote the establishment of Community Food and Fodder Banks by SHGs, to enable the needy to borrow grain when required and repay soon after harvest. Community Food Banks will also help to widen the food basket by including locally grown millets, legumes and other food crops. Such underutilized or “orphan” crops are also often rich in protein, minerals and vitamins.

An allocation of Rs. 75 crore is recommended for setting up 10000 Food Banks on priority basis in 38 of the 150 districts where the SC/ST population is more than 50 percent, in 2005-06 as discussed in detail in Chapter II. In addition, an allocation of Rs. 25 crore is recommended for setting up Community Fodder banks. Livestock and livelihoods are intimately related and therefore it is equally important to provide for setting up fodder and feed banks in the 150 districts and other arid and semiarid areas. Landless labourers have to essentially depend on stall-fed animal husbandry due to lack of grazing land. Fodder Banks are very crucial in such areas for sustenance of livestock. The limited experience of the M S Swaminathan Research Foundation in setting up community managed Fodder banks in Ladakh shows that they are of great relevance and use to communities in these areas.

f) Launch a home nutrition garden movement for the cultivation and consumption of fruits and vegetables and also link the Horticulture and Dairy Missions with the Nutrition Security programme. High value dairy, fruit and vegetable production and marketing will also lead to an increase in the income of farmers.
g) **Fighting Hidden Hunger**

More than a third of the country’s population, particularly women and children suffer from micronutrient deficiencies, especially Iron, Vitamin A and Zinc. Along with a frontal attack on poverty induced endemic hunger, a movement to eradicate hidden hunger caused by the deficiency of micronutrients in the diet should be launched. All Antyodaya households may be supplied with either a Vitamin premix or multiple fortified salt. The annual cost of such support will be about Rs.200 per family of 5 persons per year. **A provision of Rs.200 crore may be made in the budget for fighting iron deficiency anaemia among pregnant women and other micronutrient deficiencies like zinc, iodine and Vitamin A.** The hidden hunger elimination programme can be implemented through Panchayats and local bodies.

h) **Drinking Water and environmental hygiene**

Clean drinking water is becoming a luxury. It is important that the programmes of the Rajiv Gandhi Drinking Water Mission are implemented with speed, with the active involvement of Panchayati Raj institutions. Provision of toilets and improvement of environmental hygiene and sanitation require utmost priority.

i) **Hunger Free India**

**Set up a National Committee for a Hunger Free India** under the Chairmanship of the Prime Minister, with the Union Minister for Food and Agriculture and Co-Chair, for preparing a road map for launching a **National Food Guarantee Programme**, combining the features of Employment Guarantee and Food for Work Programmes. The National Committee should include in its membership Chief Ministers of States characterized by the high incidence of hunger hot spots.

The aim of the **National Food Guarantee Programme** is to enable every child, woman and man to have an opportunity for a healthy and productive life. While nutritional safety net programmes are a must at present, ultimately, every one should be enabled to earn his or her daily bread. This will call for a revolution in sustainable livelihood opportunities.
If the above programme is implemented with dedication, it should be possible to achieve a substantial freedom from endemic and hidden hunger by 15th August 2007 which marks the 60th anniversary of our independence.
CHAPTER X
LIVESTOCK AND LIVELIHOODS

The livestock sector plays a vital role in the rural economy of India. Also, the ownership of livestock is more egalitarian. Unlike land, the poor own nearly 80% of the livestock. Therefore, livestock and livelihoods have an intimate relationship particularly in arid and semi-arid areas. The most important sector is dairy, which alone contributes approximately Rs 100,000 crore to GDP. Relative to this huge contribution, investment in the dairy sector has been extremely low. The dairy industry provides employment to 18 million people (9.8 million primary and 8.6 million subsidiary employment), not including persons employed in sale, re-processing and transport of animal products at secondary market level. Of these, 70% are women and 67% have no access to land, credit or technology. Of the 70% of rural households that own livestock, the vast majority are either landless or marginal farmers. Therefore, economic development of the dairy industry can be a powerful lever for increasing rural income and employment as well as eradication of poverty.

2. The dairy sector is also vital for abolishing malnutrition and achieving food security. In a country where 42% of the population consume only a lacto-vegetarian diet and most of the rest of the population consume comparatively low levels of animal protein, milk products constitute a major source of protein required for a balanced diet. Per capita milk consumption in India has risen dramatically over the past three decades but still remains 25% below the world average. This figure appears even less adequate in view of the low levels of consumption of non-dairy protein.

The growth of the dairy industry has largely been achieved by the organization of producers processing and marketing cooperatives, the promotion of crossbred stock and delivery of veterinary services. Yet, only 35% of milk production is in the organized sector, which means that most dairy farmers lack access to these critical services. At the same time 70% of India’s milk production is generated by only seven States, indicating
that there is still substantial scope for extending the White Revolution to low production regions.

While India’s total milk production is the highest in the world, productivity per animal is extremely low by international standards. Milk yields of indigenous animals range from a high of 7.5 kg per day in Gujarat to 5 kg or less in some areas. Yields of breedable cows remain more than 60% below world averages and a third to two-thirds lower than average yields in most developed countries. The most important factors contributing to the low yields are the poor genetic stock of the milch cows and the lack of nutritious fodder and feed. In spite of an extensive breeding programme, out of approximately 220 million cattle in the country, only about 10% are cross-bred.

The most significant deficiency in the dairy industry is what the Planning Commission’s Working Group on Animal Husbandry & Dairying termed the “alarming gap between supply and demand” for fodder. It is estimated that current levels of fodder production are sufficient to meet the needs of only 47% of India’s animal population. Total production of dry and green fodder in the country is approximately 900 million tonnes. Even assuming that the entire quantity is used for feeding the cattle population, it works to only 10 kg per animal per day, as against a requirement of 35-40 kg for optimal milk production. Put simply, India’s animal population is grossly underfed.

3. The primary cause for this deficit is the lack of a well-organized system for production and distribution of nutritious fodder crops. Crop residues such as paddy straw, which constitute the major portion of animal feed, lack the nutritional content required for healthy growth and high productivity. The portion of harvested crop residues is also declining with the spread of mechanized harvesting. These are however opportunities for enriching rice straw and other cellulosic material with urea and molasses.

The area under permanent pastures is declining and productivity is falling due to overgrazing. The greatest potential for increasing the availability of nutritious fodder is by intensive cultivation of hybrid fodder crops. Few farmers recognize that the cultivation of enriched fodder grasses can be as remunerative as sugarcane cultivation and not subject to the same vagaries and fluctuations as the sugar industry. High yielding
varieties of fodder such as Bajra-Napier Hybrids and Lucerne in combination can yield about 400 tonnes per ha. under irrigated cultivation and return a net profit of Rs 35,000 per ha. or more on a cultivation cost of Rs 10,000 to 12,000. Since even small areas can be cultivated, even marginal farmers can generate high incomes from this crop. Fodder grasses can also be cultivated as an intercrop with jatropha or as a dryland crop, returning a net income of Rs 7500 per ha. Dairying and fodder production combined offer enormous potential for raising farm incomes on irrigated lands. Sylie-pastoral systems are ideal in many semi-arid areas.

The enormous economic potential of cultivated fodder production has been obscured by the fact that the buyers for fodder are among the poorest section of the population. The absence of an organized market for bulk quantities of fodder grass has been a significant deterrent to widespread commercial cultivation of fodder crops. This can be remedied by utilizing the dairy cooperatives as marketing and distribution organizations for fodder crops. A contract farming model can be developed by the dairy industry similar to the system of registered crops adopted by the sugar industry. This can provide access to bank credit, quality inputs, an assured floor price and guaranteed market for fodder growers. At the same time, the dairy cooperatives can agree to supply fodder grasses to their members in exchange for milk supplied, ensuring a ready channel for distribution and a means for impoverished dairy farmers to finance the increased dietary inputs required to raise their milk production and incomes. Loans for procurement of milch animals can also include a allocation for supply of fodder in kind and in exchange for milk through the local dairy cooperative.

Landless agricultural labour families can take to stall-fed animal enterprises, provided they are helped through Fodder and Feed Banks. In the cold desert area of Ladakh, fodder is a major constraint for Pashmina sheep. The establishment of Fodder and Feed Banks can help to promote higher productivity of sheep.

4. Business Plan for Fodder Development

1. Objective:
   a. Increase productivity of milch cows through improved nutrition.
b. Raise the incomes of dairy farmers.

c. Introduce leguminous fodder crops like berseem and lucerne in the rotation.

d. Raise the production of fodder in the country by 50 percent.

2. Strategy:

a. Introduce a contract farming system for fodder production by which dairy cooperatives and private dairies register cultivation of fodder crop lands in the same manner that sugar factories register sugarcane.

b. A tie-up between the dairies, the growers, financial institutions and input suppliers can ensure timely access to credit, quality inputs provided in kind and an assured market at remunerative prices.

c. Dairies can also be required to operate nurseries for the production of fodder seeds.

d. Veterinary and Animal Science Universities should help to establish Farm Schools for providing integrated training on breeding, feeding, management of diseases and marketing.

3. Actions Required by Government:

a. Field level demonstration plots should be established in all dairy regions to demonstrate the productivity and profitability of hybrid green fodder crops and fodder legumes and popularize their cultivation.

b. Establish a mandatory requirement for all dairy cooperatives to contract with farmers for production of fodder equivalent to 25% of the estimated total consumption of fodder by cooperative members.

c. A Livestock Food Corporation may be set up jointly with NDDB, SFAC and NABARD to stimulate and support SHGs in the production and consumption of nutritious fodder and feed by large and small ruminants.
d. The production of quality fodder seed could be outsourced to private growers on a buy-back arrangement, subject to quality certification of the seed by appropriate government agencies.

e. Special bank credit schemes should be made available to dairy farmers whereby they can obtain loans for fodder in kind on a daily or weekly basis in exchange for payment or delivery of milk.

f. NDDB can help to organise Farm Schools for Dairying in the farms of outstanding farm women and men who have mastered the science and dairy farming.

5. **Poultry Farming**

In the past, several small-scale, rural poultry units, promoted under the Integrated Rural Development Programme (IRDP) and other employment-oriented schemes have not been so successful, mainly due to:

a. Uneconomical size of the farms

b. Lack of training

c. Inadequate technical support

d. Inadequate marketing support

e. Absence of proper financial/managerial guidance

To overcome these deficiencies and to help the small scale rural poultry units operate successfully, we propose the concept of **Poultry Estates**.

The salient features of this concept are as under:

a. There would be a Central Unit – a Mother Unit – located in a cluster of villages.
b. Under the umbrella of this mother unit, there would be several small Production units, each owned and managed by an individual farmer or a single family or a self-help group.

c. The mother unit would take care of all the critical aspects of the operations like, brooding and rearing up to point of lay, vaccination etc. and then supply the ready – to – lay birds to the individual entrepreneurs.

d. The participants would then take care of the simple aspects of the operation like feeding and watering of the birds, and collection of eggs.

e. The mother unit would also prepare and supply balanced feed; provide technical assistance; and marketing support.

f. The mother unit would also handle the finance i.e. it collects the eggs, markets them; and out of the proceeds, after deducting the cost of birds, feed, etc., and repayment to the bank, would pay the balance to the concerned small scale poultry farmers.

The concept of Poultry Estate thus involves decentralised production supported by key centralised services in such areas as breeding, feed production, disease management and marketing.

6. General Recommendations

There is urgent need for launching a Sanitation Literacy programme among all engaged in farm animal rearing (cows, buffalos, sheep, poultry) to avoid infection of milk or eggs with Salmonella or other mycotoxin producing organisms. If the sanitary conditions under which farm animals are reared are not improved, it will not be possible for us to capture or retain external markets.

Eternal vigilance is the price of a stable and successful livestock industry. It is important to screen rigorously imported animal products for pathogens which could spell disaster to our farm animals including poultry. SPS measures should be such that invasive alien species of pests and pathogens do not get entry into India.
CHAPTER-XI

BEYOND TSUNAMI: SAVING LIVES AND LIVELIHOODS

Recommendations for Alleviating Fisher and Farm Families’ Distress and for Rehabilitation

1. The Prime Minister has rightly stressed that every calamity presents also an opportunity for equipping ourselves to face with greater confidence and competence similar calamities in the future. The Government of India has announced that a Tsunami Early Warning System as well as a National Disaster Management Authority will be set up soon.

2. Relief measures are in progress on an unprecedented scale, thanks to intensive and extensive efforts by the Central and State Governments, national and international Civil Society Organisations (NGOs), Private and Public Sector Industry, academia, the mass media and bilateral and multilateral donors.

3. Fifteen days after the titanic Tsunami hit our coast and islands, we are in a position to begin rehabilitation efforts in three time dimensions.

A. **Immediate (January – March, 2005)**
   - Water, shelter, sanitation, health and revival of livelihoods.
   - Psychological rehabilitation
   - Repair of catamarans
   - Achieving convergence and synergy among all on-going programmes with similar objectives *(this is an urgent task)*

B. **Medium Term (2005-07):**
   - Ecological rehabilitation
• Agronomic rehabilitation
• Economic rehabilitation
• Disaster preparedness, mitigation and management

C. **Long Term (2005-10):**

• Strengthening environmental defense systems

• Enlarging opportunities for sustainable livelihoods based on a pro-nature, pro-poor, pro-women orientation to technology development and dissemination.

• Improving the productivity, profitability and sustainability of agriculture and fisheries.

A. **Immediate:**

**Psychological Rehabilitation:**

It will be necessary to form teams of men and women psychiatrists and trauma counsellors who can cover the severely affected areas during the next few weeks to bring comfort and confidence to those who have lost their dear and near ones. Fishermen will have to be assisted in overcoming their fear of the sea. Farmers also need technical help and moral support. The professional / counseling sessions could be organized by appropriate civil society organizations in association with Panchayats. Those living in relief camps need particular attention. To the extent possible, destitute women and orphaned children should be rehabilitated in their own community and should not be herded in destitute homes, either old or new.

**Livelihood Rehabilitation:**

*A Special Food for Livelihood Revival and Eco-protection programme* should be initiated immediately in all the affected areas. Such an open-ended Food for Work Programme, which can be sanctioned for a year in the first instance, **should aim to create assets for the Tsunami ravaged families**, and should not solely be community centred, as in the
case of normal Food for Work programmes. The concept of work under this special programme should include items such as:

a. Rebuilding houses
b. Repairing and building fishing boats and vessels
c. Rebuilding jetties, access roads and market yards
d. Rebuilding schools
e. Rebuilding health care centres
f. Establishing day care centres and crèches for children
g. Eco-restoration programmes like rehabilitation of mangrove wetlands and reclamation of soils inundated with sea water.

The precise priorities can be developed for each village in consultation with local Panchayats and affected families. **It is suggested that about 300,000 tonnes of food grains may be allotted immediately for this special programme,** which will allow Tsunami affected families to have access to food while they are rebuilding their lives and livelihoods, as well as essential infrastructure for human resource development.

**B. Medium and Long-term:**

These programmes should cover all families along the coast – both fisher and farming families, including the families of those who have no assets like land, livestock or fish pond. They fall under three broad groups.

i. **Strengthening the ecological foundations of sustainable human security:**

This programme will include the following:

a. Initiating a coastal *Bio-shield* movement along coastal areas, involving the raising of mangrove forests, plantations of *casuarina, salicornia, laucaena, atriplex,*
palms, bamboo and other tree species and halophytes which can grow near the sea. They will serve as speed-breakers under conditions of coastal storms, cyclones and Tsunami. They will in addition serve as carbon sinks, since they will help to enhance carbon sequestration and thereby contribute to reducing the growing imbalance between carbon emissions and absorption. Mangroves are very efficient in carbon sequestration. They also promote sustainable fisheries by releasing nutrients in the water. In addition, they will provide additional income and make coastal communities eligible for carbon credit.

The Coastal Bio-shield can also involve agro-forestry programmes, like the intercropping of casuarina with hybrid pigeon pea (cajanus cajan) or Red gram, to be undertaken by farming families. Thus, the Bio-shield movement will confer multiple benefits to local communities as well as to the country as a whole.

b. **Promote Peoples’ Participation** in the conservation and enhancement of mangrove and other coastal wetlands, as well as coral reefs and coastal and marine biodiversity.

*A Participatory Mangrove Forest Management Programme* on the basis of the guidelines already developed by the M S Swaminathan Research Foundation (MSSRF) should be introduced. The Joint Mangrove Forest Management is based on the successful model of Joint Forest Management already in progress in most parts of India. The super cyclone havoc in Orissa and the current Tsunami tragedy have created widespread awareness among the people on the role Mangrove forests play in reducing the fury of cyclonic storms and tidal waves.

c. Promote the organization of *Community nurseries* of Mangrove species and other appropriate tree species chosen under the coastal Bio-shield and agro-forestry programmes. Techniques for raising such nurseries have been standardized by MSSRF. Community nurseries can be raised under the auspices of both Forest Departments and Panchayats. Where appropriate, such nurseries can be raised on
the basis of a buy-back arrangement. Farm families can raise nurseries / produce seeds of crops chosen for the agro-forestry programme.

d. **Regeneration of Fisheries and fostering a sustainable fisheries programme:**

The new fishing vessels and nets should be designed in a manner that they do not disrupt the fish life cycle by catching young ones and also do not destroy seagrass beds, which serve as habitats for dugongs. The calamity provides an opportunity for achieving a paradigm shift from unsustainable to sustainable fisheries.

e. **Raising artificial coral reefs:**

The work done in the Gulf of Mannar area indicates that artificial reefs can stimulate fish breeding and revival. These can be laid and managed by fisher self-help groups (SHGs). NABARD can develop a special programme to promote the growth of such SHGs.

f. **Managing Marine Biosphere Reserves in a Trusteeship Mode:**

A trusteeship pattern of management of coastal bio-resources should be fostered. This will help local communities and government departments to manage unique biological resources in a trusteeship mode, *i.e.* people considering themselves as trustees of such assets with a commitment to conserve them for posterity. A beginning has been made in the Gulf of Mannar Marine Biosphere Reserve, but this system needs to get institutionalized all along the coast as well as in the Andaman and Nicobar and Lakshadweep group of islands.

g. **Housing for Fisher families:**
The new houses should respect the 500 meter restriction and should be cologically designed. If all fisher folk had their housing sites on the landward side of coastal roads, the death toll as a result of Tsunami would have been much lower. Anticipatory action against sea level rise also demands a human security driven design of coastal habitations. A group of architects should be assembled for this purpose immediately.

h.  *Construction of sea walls and dykes:*

The construction of permanent sea walls can be taken up in places where there is sea erosion due to heavy anthropogenic pressures. The locations for such non-living barriers should be determined on the basis of a carefully conducted erosion vulnerability analysis.

i.  *Agronomic rehabilitation : Reclamation of salinised soils:*

Sea water ingress has led to soil salinisation in some areas. A scientific Team consisting of representatives of Agricultural Universities, ICAR (Central Soil Salinity Research Institute) and CSIR may be set up to survey the areas, study the nature and severity of the problem and suggest remedial measures. **This should be done within the next two months, so that farmers are able to resume normal farm operations without losing a crop season.**

The serious loss of life and property caused by Tsunami highlights the vision and wisdom of Smt Indira Gandhi when nearly 24 years ago, she took steps to ensure that no permanent construction is permitted within 500 meters of the high tide. We should not only strengthen this national resolve, but also **develop a code of conduct for construction beyond 500 meters.** Such a code can consist of a
package of rewards for initiatives in the areas of sunward oriented buildings, energy efficient construction, use of wind / tidal / solar energy, rainwater harvesting, use of local construction material, effluent treatment and use of biodegradable material. The coastal ecological security literacy programme should bring to the attention of builders the opportunities now available for mainstreaming ecology in building design and construction.

k.  

**Vulnerability Mapping:**

Based on an analysis of 100-year data, the areas prone to cyclones and other natural disasters can be mapped. Priority may be given to such areas in erecting bio-shields and in undertaking eco-restoration and erosion prevention measures. Human and agricultural vulnerability to potential changes in sea level should also be mapped. A Consortium of R & D institutions set up by the Department of Ocean Development, Department of Science and Technology, and the Indian Meteorological Department, Government of India, should take up this task immediately.

k.  

**Sustainable Management of Coastal Land and Water Resources:**

Scientific land and water use planning will have to be done to prevent salinisation of ground water. Land and water use patterns based on principles of ecology, economics and social and gender equity will have to be prepared by Panchayats with the help of ICAR (National Bureau of Soil Survey and Land Use Planning), the concerned Farm University and the Forest, Fisheries and Agriculture Departments of State Governments.
ii. Rehabilitation of Livelihoods and fostering sustainable livelihood security:

The sustainable livelihood security strategy should be based on the principles of *social inclusion and gender equity*. They should cover both fisher and land based farming communities as well as landless labour families. The following steps are needed:

a. *Aquarian Reform:*

This is essential to foster harmony in the use of living aquatic resources by artesenal fishermen operating catamarans, and commercial families operating mechanized fishing boats and trawlers. The major aim of the Aquarian policy should be:

- Conservation of living aquatic resources
- Sustainable use
- Equitable sharing of benefits
- Harmony between artesenal and mechanized fishing.

b. *Integrated capture and culture fisheries : Sea Water Farming:*

Fisher families, particularly women, can take to the rearing of prawns and suitable salt tolerant fish species in canals along the sea coast, using low external input sustainable aquaculture (LEISA) techniques. Agro-aqua farms involving the concurrent cultivation of tree species and rearing of fish and prawns can be promoted to enhance income and employment opportunities. The Tsunami tragedy should lead to the emergence of new sea farming communities, well versed in both production and post-harvest technologies, quality management and value addition.
c.  *Establishment of Coastal Biovillages:*

The economy of coastal villages can be strengthened through the biovillage model of rural development. This involves the sustainable use of natural resources and introduction of market driven non-farm enterprises as well as value addition to primary products. It also involves a paradigm shift from unskilled to skilled work, resulting in the addition of economic value to time and labour. The micro-enterprises chosen for being undertaken by SHGs with micro-credit support should be based on both value addition to under-utilised resources and market demand. The coastal Biovillage movement to be fostered by Panchayati raj institutions should be based on a pro-nature, pro-poor and pro-women orientation to enterprise development and adoption. An important component of coastal biovillages should be the establishment of *Aquaculture Estates* which can help to confer the power of scale to fisher families in the production, processing and marketing of fish.

d.  *Establishment of a coastal grid of Farm Schools and Demonstration Centres:*

Farm and Fisher families practising the use of natural resources based on principles of ecological economics can be chosen for establishing Farm Schools. Lateral learning among farmers and fisher families will be more effective than formal institutional learning. Both can go together. Demonstration of environmentally sound sea farming techniques should also be organized.

iii.  *Network of Rural Knowledge Centres (RKC):*

The crucial importance of timely information is now widely recognized in minimizing the loss of life caused by disasters like Tsunami. *It is therefore essential that a network of Rural Knowledge Centres is established all along the coast as soon as possible.* Such RKC's will use in an integrated way the internet, community (FM) radio, cable TV and the vernacular press. They will provide
both generic and dynamic information and will help to disseminate locale-specific and demand driven information. They will also serve as an integral part of the National Early Warning system. They can empower fisher, farm and other coastal inhabitants with information on their entitlements to government programmes and attend to other essential needs relating to education, health, weather and market.

*Training should be imparted* in disaster preparedness and management, as well as in trade and quality literacy. Food safety issues and codex alimentarius standards should be highlighted in the training programmes. Even if there is an efficient early warning system, the information will have to reach the unreached, particularly fishermen in sea. Therefore, a network of community radio (FM) centres will have to become an integral part of the coastal area knowledge connectivity. The policy support needed for this programme has already been described and spelt out in detail in Chapter VIII of the Report.

iv. **Resource Centres for Capacity Building:**

There is need for establishing a network of capacity building centres along the coast. A Resource Centre for Mangrove Forest Conservation, rehabilitation and expansion is urgently needed. There is need for preparing training modules in local languages on a wide range of topics relating to both ecological and livelihood security. Training programmes will have to be organized for SHGs who wish to take up work in the areas of raising community nurseries, eco-restoration, reclamation of salt affected soils, market-led enterprise development and managing Rural Knowledge Centres.

Education, social mobilization and regulation will have to become the pillars of the coastal ecological and livelihood security systems. The RKC’s will provide an opportunity to professionals for sustained engagement with local communities.

v. **Conclusions:**
The Tsunami disaster has provided an unique opportunity for launching through public-private sector partnership an integrated psychological, ecological, agronomic and livelihood rehabilitation programme. To succeed, such programmes should be people centred and managed by local communities with appropriate guidance and support from government and panchayati raj institutions. Government agencies, academia, and local communities should jointly develop Integrated Coastal Zone Management plans which would help to transform sustainable development from a desirable objective into a practical reality.
MSS/DB/
15 January 2005

Hon.ble Shri Manmohan Singh
Prime Minister of India
Prime Minister's Office
New Delhi 110 001

Dear Dr. Manmohan Singh

Sub: Reports of the National Commission on Farmers (NCF)

The National Commission on Farmers (NCF) submitted last month its first report titled “Serving Farmers and Saving Farming” dealing with ten urgent issues. Early this month, NCF also finalised its recommendations for assisting fisher and farm families affected by the Tsunami disaster to regain their livelihoods. This report titled, “Beyond Tsunami: Saving Lives and Livelihoods” was forwarded to you last week.

For facilitating speedy decisions on items for which financial provision is needed in the Union Budget for 2005-06, as well as items relating to policy and administrative reforms, I enclose a concise statement. In my view, the agrarian crisis will get aggravated if action is not taken on these recommendations. The six basic principles which have guided our recommendations are:

- Affordability.
- Actionability.
- Accelerated agricultural progress through bridging the wide gap between prevailing scientific know-how and field level do-how.
- Assisting Government to maximize the social impact and benefits of its numerous ongoing programmes involving large financial outlays through convergence and synergy in delivery systems.
- Assisting farm families to maximize the benefits of their resource endowments in the areas of land, water, labour and capital.
• Promoting a symbiotic alliance with rural families by implementing the provisions of article 243G of the 11th schedule of Constitution 73rd Amendment Act of 1992.

With warm regards,

Yours sincerely,

M S Swaminathan

Encl: a/a
National Commission on Farmers (NCF)

Recommendations needing urgent attention and action in the Union Budget for 2005-06

Details are contained in the Report “Serving Farmers and Saving Farming” submitted in December 2004.

Chapter-II

1. Assisting local communities to establish 10,000 Community Grain Banks in the hunger hot-spots in the 150 districts identified for the National Food for Work Programme – Outlay: Rs. 75 crore.

2. Parivar Bima and other policies for healthcare, accidents and loss of property – Outlay: Rs. 260 crore.

3. Rural Insurance Development Fund – Outlay: Rs. 50 crore.

   Recommended total Allocation: Rs. 385 crore.

Chapter-III

4. Water for Agriculture

   - Implement a Million Wells Recharge Programme during 2005-06, by providing a rebate in the rate of interest provided under the enhanced agricultural credit programme.

   - Restoring water bodies and promoting water harvesting – Outlay: Rs. 70 crore for fostering a community water saving and sharing movement.

5. Soil Health Enhancement

   Establish a National Network of advanced soil testing laboratories capable of testing large volumes of soil samples for 16 macro and micronutrients – 1000 laboratories in all parts of the country, with 500 of them being located in dry farming areas, where there is scope for doubling average yields immediately through addressing the deficiencies of micro-nutrients in the soil, in addition to attending to the needs for N, P & K. Cost Rs. 50 lakhs per laboratory – Outlay: Rs. 500 crore.
6. Bridging the growing gap between scientific know-how and field level do-how:

Establish 50,000 Farm Schools in the farms of farmer-achievers who have mastered the art and science of enhancing the productivity, profitability and sustainability of crop and animal husbandry, horticulture, fisheries and agro-forestry. Such farmer to farmer learning has the added advantage of mainstreaming cost-risk-return considerations in farming, since the experience of fellow farm men and women has higher creditability. Government contribution will be in the form of support to the construction of hostels in the farms of participating Farmer Trainers and some remuneration for the time and efforts of the farm family. Provision will also have to be made for the travel, boarding and lodging expenses of farmer-trainers. Priority may be given to horticulture, pulses, oilseeds, millets, tuber crops, medicinal plants, cotton, dairy and poultry farming and inland and coastal fisheries – Outlay: Rs. 150 crore.

7. Capacity building in post-harvest technology and value addition:

A post-harvest technology wing may be added to the existing Krishi Vigyan Kendras (KVK), in order to bridge the huge gap between production and post-harvest technologies, particularly in horticulture resulting in considerable post-harvest losses as well as loss in opportunities for value-addition – Outlay: Rs 100 crore.

8. Enhancing yield, income and employment in dryland farming areas

- 2000 Largescale Farming systems demonstrations.
- 3000 factor demonstrations to introduce new implements, hybrid arhar and new agronomic practices, particularly the application of micronutrients.
- 6000 Small holders Estates.
- 1500 Seed Banks

Outlay: - Rs. 230 crore.

**Recommended total Allocation: Rs 1050 crore**

Chapter-IV

9. New Deal for Women in Agriculture

- Ensuring women’s access to credit, including Kisan Credit Cards.
- Gram Panchayat Mahila Fund. Outlay: Rs 200 crore
- Childcare and other support services for women in agriculture.
- Supplementary nutrition for 0-2 years age group children. Outlay: Rs 500 crore
- Support to Women Self-Help Groups. Outlay: Rs 25 crore
- Engendering the curriculum of Agricultural Universities etc. Outlay: Rs 1 crore

**Recommended total Allocation: Rs. 726 crore.**
Chapter-V
10. Strengthening and expanding the Horticulture Revolution

- Small Farmers’ Horticulture Estates
- Post Harvest Management.
- Production of good quality seeds and planting materials.
- Imparting quality literacy.

Provision for these items will have to be made in the National Horticulture Mission already proposed by the Ministry of Agriculture.

Chapter-VI
11. Enhancing national competitiveness in Cotton

- Organisation of 100 Small Farmers’ Cotton Estates, each covering 1000 ha. Outlay: Rs 175 crore
- Integrated Technology. Demonstrations including value addition to cotton biomass. Outlay: Rs 75 crore
- Appointment of an overall Mission Director to coordinate the activities in progress under 4 Mini Missions

**Recommended total Allocation: Rs. 250 crore (in addition to the provision for the Cotton Technology Mission).**

Chapter-VII
12. Strengthening Sanitary and Phyto-sanitary Measures

Imparting quality and trade literacy, meeting **codex alimentarius** standards and preventing the introduction of invasive alien species

**Recommended total Allocation: Rs.60 crore.**

Chapter-VIII
13. Every Village a Knowledge Centre

- Mobilizing Information Communication Technologies (ICT) for the knowledge empowerment of rural families in areas relating to weather, water, health, education, nutrition, agriculture, markets and government entitlements through Village Knowledge Centres. Outlay: Rs 750 crore

- Establishment of a National Digital Highway for Rural Livelihood Security. Outlay: Rs 100 crore

- Establishment of Farmers’ Distress Call Centres. Outlay: Rs 100 crore
• Establishment of 20,000 Rural Knowledge Centres. Outlay: Rs 500 crore

  **Recommended total Allocation: Rs.1450 crore (most of it from the USO fund)**

**Chapter-IX**

14. Hunger-free India

• Supplementary nutrition to adolescent girls, pregnant women and 0-2 age group children. Outlay: 2.5 lakh tonnes of foodgrains

• Nutrition support to HIV/AIDS and Tuberculosis affected children, women and men. Outlay: 1.0 lakh tonnes of foodgrains

• Elimination of hidden hunger caused by the deficiency of micro-nutrients. Outlay: Rs 200 crore

• Establishment of Community Food & Fodder Banks. Outlay: Rs 25 crore for fodder Banks

  **Recommended total Allocation: Rs.225 crore and 3.5 lakhs tonnes of foodgrains.**

**Chapter-X**

15. Livestock and Livelihoods

• Organisation of a Livestock Food Corporation of India. Outlay: Rs 100 crore

• Establishment of Small Farmers’ Poultry Estates

  **Recommended total Allocation: Rs.100 crore**

**Chapter-XI**

16. Beyond Tsunami: Saving Lives and Livelihoods

• Food for Livelihood Revival and Eco-protection programme – 300,000 tonnes of food grains.

• Psychological, ecological, agronomic and economic rehabilitation programmes – Fostering a Coastal **Bio-shield** programme for minimising the fury of cyclonic storms and tidal waves.

• Fostering a **Coastal Biovillage Movement** for providing multiple livelihood opportunities.

• Organising a network of Rural Knowledge Centres in Coastal villages.
Aquarian Reforms for promoting sustainable fisheries (funds to be provided under the various rehabilitation programmes now being planned).

**Recommended total Allocation: Rs 3 lakh tonnes of food grains and funds provided for rehabilitation.**

National Commission on Farmers (NCF)

Maximising the benefits of ongoing Government Programmes

Summary and Suggestions for Policy and Management Reform

(Details are contained in the Report)

1. Organise a **S&T Alliance** for Rural Livelihood Security for providing technical backstopping to the National Food for Work and Rural Employment Guarantee programme.

2. Form a **National Federation of Farm Technology Missions**, chaired by a **practising farmer** to bring about convergence and synergy among numerous on-going Technology Missions, with a watershed serving as the hub for the fusion of action under diverse programmes.

3. Set up a multi-stakeholder National Steering Committee to oversee the development of rural and agricultural insurance.

4. Set up a **Commission for Sustainable Livelihood Security in Dry Farming Areas**, headed by a farmer-achiever.

5. Establish a **National Board for Women in Agriculture**, chaired by the Union Minister for Food and Agriculture, with Union Ministers for Women and Child Development and Panchayati Raj serving as Co-chairs.

6. Establish a multi-stakeholder **National Horticulture Council** with Union Minister for Agriculture as Chairman.

7. Set up a **National Cotton Council** with the Union Minister for Agriculture as Chairman and the Union Ministers for Textiles and Commerce as Co-chairs.

8. Redefine and enlarge the role of the Cotton Corporation of India.

9. Establish a **Food Safety Council of India** with the Union Minister for Food and Agriculture as Chairman and the Union Ministers for Health and Commerce as Co-chairs.

10. Develop a new policy to encourage the spread of **Community Radio (FM)** in rural areas and organise a **National Digital Gateway for Rural Livelihood Security**.
11. **Set up a National Committee for a Hunger-free India** under the chairmanship of the Prime Minister, with the Union Minister for Food and Agriculture as Co-chair for preparing a road map for launching a **National Food Guarantee Programme**, combining the features of the Employment Guarantee and Food for Work programmes on 15 August 2007, which marks the 60th Anniversary of our Independence. The National Committee for a Hunger-free India should include in its membership Chief Ministers of States characterised by the high incidence of hunger hot spots.

12. Set up a Committee under the chairmanship of Union Home Minister, to monitor progress in the implementation of the integrated rehabilitation strategy suggested by NCF for Tsunami affected regions.

TERMS OF REFERENCE
FOR
NATIONAL COMMISSION ON FARMERS

◆ Work out a comprehensive medium-term strategy for food and nutrition security in the country in order to move towards the goal of universal food security over time.

◆ Propose methods of enhancing the productivity, profitability, stability and sustainability of the major farming systems of the country based on an agro-ecological and agro-climatic approach and the harnessing of frontier technologies.

◆ Bring about synergy between technology and public policy and recommend measures for enhancing income and employment potential in rural areas through diversification, application of appropriate technology including IT for information on market, weather, credit facilities and e-commerce, training and market reforms.

◆ Suggest measures to attract and retain educated youth in farming and recommend for this purpose; methods of technological upgrading of crop husbandry, horticulture, animal husbandry, fisheries (inland and marine), agro-forestry and agro-processing and associated marketing infrastructure.

◆ Suggest comprehensive policy reforms designed to enhance investment in agri-research, substantially increase flow of rural credit to farmers including small and marginal, triggering agricultural growth led economic progress, which can lead to opportunities for a healthy and productive life to rural families.

◆ Formulate special programmes for dryland farming for farmers in the arid and semi-arid regions, as well as for farmers in hilly and coastal areas in order to link the livelihood security of the farming communities living in such areas with the ecological security of such regions. Review in this context, all ongoing Technology Missions like those relating to pulses, oilseeds, maize, cotton, watershed etc. and recommend methods of promoting horizontal integration of vertically structured programmes. Also suggest credit-linked insurance schemes which can protect resource poor farm families from unbearable risks. Further, suggest methods of strengthening and streamlining the National Horticulture Development Board.

◆ Suggest measures for enhancing the quality and cost competitiveness of farm commodities so as to make them globally competitive through providing necessary facilities and application of frontier science and promote quality literacy for codex alimentarius standard, sanitary and phyto-sanitary measures among farmers through reorienting and retooling extension machinery. Also suggest methods of providing adequate protection to farmers from imports when international prices fall sharply.

◆ Recommend measures for the credit, knowledge, skill, technological and marketing empowerment of women, taking into consideration the increasing feminization of agriculture and the proposed conferment of right to land ownership.

◆ Suggest methods of empowering male and female members of elected local bodies to discharge effectively their role in conserving and improving the ecological foundations for sustainable agriculture like land, water, agro-biodiversity and the atmosphere with priority attention to irrigation water.

◆ Consider any other issue, which is relevant to the above or is specially referred to the Commission by Government.
The Commission is to submit a medium term policy for food and nutrition security in the country in order to move towards the goal of universal food security over time within the next three months and to submit its recommendations on other Terms of Reference as soon as practicable and in any case on or before 13th October, 2006. The Commission, however is permitted to submit interim reports on any of the Terms of Reference it deemed fit or expected of it.

[Ministry of Agriculture Resolution No.8-2/2003-Policy(ES) dated 18th November, 2004]
COMPOSITION OF THE
NATIONAL COMMISSION ON FARMERS

The composition of the reconstituted National Commission on Farmers is as under:-

Chairman
Prof. M.S. Swaminathan

Full-time Members
Dr. Ram Badan Singh
Shri Y.C. Nanda

Part-time Members
Dr. R.L. Pitale
Shri Jagadish Pradhan
Ms. Chanda Nimbkar (Yet to join)
Shri Atul Kumar Anjan

Member Secretary
Shri Atul Sinha

[Ministry of Agriculture Resolution No.8-2/2003-Policy (ES) dated 18th November, 2004]
EXECUTIVE SUMMARY

CHAPTER 1 - FROM CRISIS TO CONFIDENCE

Our agriculture is in a state of serious crisis. The rate of growth in food production has fallen below population growth rate. To achieve a 4% growth rate in agriculture, we must aim at a 8% growth rate in horticulture and animal husbandry. This calls for higher investment in irrigation, animal husbandry, fisheries, post-harvest technology, rural energy supply and communication. The investment in agriculture has stagnated at 1.3% of GNP during the last three Five Year Plans. If we place faces behind figures, over 400 million children, women and men belonging to families with small and marginal holdings, as well as landless labour families are in deep distress.

2. Several solutions offered in our first report on implementing a Million Wells Recharge Programme, establishing a network of advanced soil testing laboratories, setting up Farm Schools in the fields of farmer achievers, strengthening the post-harvest technology and quality literacy wings of KVKs, organizing Small Holders Horticulture Estates and Cotton Estates to harness the economies of scale, large scale demonstrations to initiate a productivity revolution in pulses, setting up a Livestock Feed Corporation of India, convergence of appropriate Technology Missions around a Watershed or the command area of an irrigation project, need to be implemented without further delay.

3. Enhancement of small farm productivity coupled with assured and remunerative marketing opportunities is the most effective means of reducing rural poverty. Among the immediate steps needed to prevent farmers’ suicides are - credit reform to enhance the total amount available for farm loans, a reduction in interest rates, linkages with technology and market and reduction in dependence on the informal sector for loans; a corpus (on the line of calamity funds) for assisting farmers affected by crop losses; expansion of crop insurance to cover the entire country and all crops; Cultivation of water intensive cash crops in “dark and grey zones” should be regulated; there should be appropriate legislation to regulate and deter the sale
of spurious seeds and chemicals; implementation of MSP for coarse cereals and pulses, which are the primary crops in rainfed drylands across the country;

5. It would be prudent to introduce a Farmers’ Livelihood Security Compact, consisting of the following integrated package of measures:
   i) Set up State level Farmers’ Commission for the purpose of ensuring dynamic government response to farmers’ problems.
   ii) Conduct Census of Suicides to have a proper understanding, assessment of reasons and count of suicides
   iii) Initiate a Paradigm shift from Micro-finance to Livelihood Finance
   iv) Debt survey to take into account newer forms of credit and indebtedness and newer forms of bondage
   v) Decide on cut-off for Debt waiver in consultation with Panchayats and farmers’ representatives in the distress hotspot areas.
   vi) Examine revival of lapsed insurance policies; there are provisions in the insurance laws that allow LIC to revive them.
   vii) The integrated family insurance policy (Parivar Bima) recommended by NCF in its first report deserves to be examined and introduced to begin with, in dry farming areas.
   viii) Revision in import policies, measures to expand farm exports and conduct of quality literacy programmes.
   ix) Swift action to overhaul the ryuthu bazars or farmers’ markets. Most of these are presently controlled not by farmers but by traders, from whose control they must be released. There is also need for introducing focused Market Intervention Schemes (MIS) in the case of life-saving crops such as cumin in arid areas.
   x) Agricultural and Animal Sciences Universities could form Hope Generation Teams (like NSS) of young male and female students who could stay in the distress villages during vacations and extend both technical and psychological support.
   xi) There is need for establishing Village Knowledge Centres (VKCs) in the farmers’ distress hotspots operated to the extent feasible by the wives or children of the farmers who had unfortunately taken their lives. These VKCs could be linked to a Block level Village Resource
Centre (VRC) with the help of the Indian Space Research Organisation (ISRO). The VRC-VKC grid could provide dynamic and demand driven information on all aspects of agricultural and non-farm livelihoods.

6. The NCF supported Travelling Workshop for **Agronomic Rehabilitation of Tsunami affected coastal agriculture** has made detailed recommendations in the areas of Soil Health Restoration, Desirable Cropping Systems, Crop Diversification and Promotion of Multiple Livelihoods and initiation of “Beyond Tsunami” Agricultural Rehabilitation Demonstration programme. Funds for the Demonstration cum Training programme may be provided from the Tsunami Relief Allocation. This will have to be done immediately, if the problems of the tsunami affected farmers are to be solved and their livelihoods revived.

7. **Indo-US Collaboration in Agronomic Rehabilitation Strategy** - The GreenLine Group, a group of scientists, professional, and technical experts from the US has offered to work closely with scientists in India and seeks a site in Tamil Nadu where they can help to start work on 100 ha of farmland. This can become an important programme to promote sharing of knowledge and technology. The timing of this project is critical to launch at the beginning of the October monsoon season. We suggest that Rs.1 crore be allotted for this collaborative programme from the Prime Minister’s Relief Fund.

8. We envisage that knowledge connectivity should be a key component of the Bharat Nirman programme designed to provide a New Deal for Rural India. The NCF proposal for **Mission 2007: Every Village a Knowledge Centre** received support in the union budget for 2005-06. We recommend that the Ministries of Rural Development and Panchayati Raj provide Rs. 50 crores each for such training and capacity building activities during 2005-06. The Union Ministry of Agriculture may also provide Rs. 50 crores annually during the next 3 years for content creation and capacity building in the areas of crop and animal husbandry, fisheries, forestry, agro-processing and marketing and for imparting quality trade and genetic literacy.

9. Several farmers’ organizations have suggested that the Ministry of Agriculture should be renamed as **Ministry of Agriculture and Farmers’ Welfare**. We recommend the serious
consideration of this suggestion since farmers’ well-being should be the main goal of the Ministry.

10. We are happy that a NDC Committee on Agriculture has been set-up under the Chairmanship of Shri Sharad Pawar. We request that the suggestions contained in this Report as well as the earlier one may kindly be examined by the NDC Committee so that appropriate action can be taken concurrently at the Central and State levels.
CHAPTER 2 - FOOD FOR ALL

Medium Term Strategy for Food and Nutrition Security with a view to move towards the goal of universal food security over time.

The Mid-term appraisal of the Tenth Plan reveals that we are lagging behind in achieving the Millennium Development Goal of halving hunger by 2015. Under-nutrition and malnutrition are still widespread. Maternal and foetal under-nutrition is resulting in the birth of babies with low birth weight. This has serious consequences for the future intellectual capital of India. Therefore building a sustainable food and nutrition security system is an urgent task.

2. The current trend of a decline in per capita food grain availability and its unequal distribution have serious implications for food security in both rural and urban areas. Going by the Union Planning Commission estimate of the proportions of population below the poverty line, a total of 260.27 million people in both rural and urban areas put together can be definitely assumed to be unable to buy sufficient food to achieve food and nutrition security.

3. Detailed analysis of the causes of food insecurity in rural and urban India have revealed that inadequate purchasing power due to lack of job/livelihood opportunities is the primary cause of endemic or chronic hunger in the country. Further, during the 1990s, the PDS has been weakened, both by repeated increases in the issue prices of food grains and by the switch to a system of targeted PDS. We recommend that people should be able to access grains from PDS whenever they want, wherever they want and in any quantity they want, subject to a few ground rules which will prevent purchase for hoarding and subsequent sale at high prices.

4. Given the magnitude of the employment problem in urban India, particularly in the small towns, there is a strong case for a National Urban Employment Guarantee Programme on the lines of the proposed National Rural Employment Guarantee Programme. The National Food Guarantee Act we are proposing will address hunger in its totality – both rural and urban.
5. **A Six Point Action Plan is outlined below for making India Hunger-Free:**

1. Reorganise the delivery of nutrition support programmes on a life-cycle basis with the participation of Panchayats and local bodies.

2. Eliminate micronutrient deficiency induced hidden hunger through an integrated food cum fortification approach.

3. Promote the establishment of Community Food and Water Banks operated by Women Self-help Groups, based on the principle “**Store Grain and Water Everywhere**”.

4. Help small and marginal farmers to improve the productivity and quality of farm enterprises.

5. Introduce support systems to SHGs to make them economically and organizationally sustainable. Establish for this purpose SHG Capacity Building and Mentoring Centres and focus on Livelihood Finance.

6. Formulate a **National Food Guarantee Act** continuing the useful features of the Food for Work and Employment Guarantee programmes and introduce it on 15 August, 2007, which marks the 60th anniversary of our independence. The Food Guarantee Act will be a powerful tool in achieving the goal of a hunger-free India.
CHAPTER 3 - FISH FOR ALL

Fisheries sector has grown at the rate of 4.3 per cent during the Ninth Plan and represents a major opportunity for growth of the Agriculture and allied sectors in particular and the GDP in general, since it already contributes 6.2 per cent of agricultural GDP and 1.4 per cent of GDP and also contributes 21 per cent of national Agricultural Exports. India already occupies fourth position in fisheries and second position in aquaculture globally and fisheries contribute export earnings of Rs.6,800 crores. The strength of the Fisheries sector consists of large under-utilized areas of fresh water tanks/ponds, lakes and derelict bodies, reservoirs, rivers, saline and brackish water resources, Exclusive Economic Zone and a large coastline. India also has a large variety of agro-climatic zones, fish fauna, research infrastructure and processing capacity.

2. Opportunities for employment and export through exploitation of our premium varieties and mariculture /ornamental fish culture/ sewage fish culture/composite fish culture etc. can be exploited provided our weaknesses like siltation/pollution of water bodies, sub-optimal management, inadequate quality control of seed and feed, inadequate exploitation of available species, and weak infrastructure for landing and marketing as well as problems of open access/multi-user conflicts/inappropriate leasing policies could be tackled. Aquarian reforms to permit optimum exploitation at ecologically sustainable levels are needed urgently along with a review of the Marine Fisheries Regulation Act of the States.

3. Inland fisheries which is already 53 per cent of our total production can be substantially boosted through greater attention to aquaculture both in fresh, saline and brackish water. This would involve production and culture of a larger range of available species, particularly for cold-water species like trout and mahseer and air-breathing fish like magur. The large potential of reservoirs can be optimally utilized for production and employment generation through better leasing policies, appropriate stocking and management and pen culture. Capture fisheries can be promoted through control of pollution of river systems, control of weeds in flood plains/wetlands etc. While inland saline soils in over-irrigated areas can be utilized for production of scampi (prawn), brackish water areas can provide substantial additional
employment and export incomes provided aquaculture is treated at par with agriculture and sound leasing policies are adopted along with reduced duties on feed and lower power tariffs. Above all, transparent quality control of feed and seed through certification cells can boost productivity. Aqua shops/Village Knowledge Centres along with pathological laboratories for better fish/shrimp health and easy bank loans/insurance can further promote this sunrise sub-sector. Design and construction of large assembly/auction markets and small hygienic shops in cities and hygienic boxes for fish sellers particularly women are important components of an efficient marketing infrastructure.

4. Marine fisheries too can see substantial growth through proper registration of all boats, demarcation and enforcement of fishing jurisdictions, and eco-friendly fishing gears/practices greater encouragement to fishing in 90-150 m depths, encouragement to pelagic and mid-water trawling and species-specific fishing like purse seining, squid jigging etc. Introduction of mother vessels for support to artesenal fisheries can improve catches and their quality. Insistence on discharge of the catch by deep-sea vessels on Indian shores can lead to optimum utilization of our processing capacity. An ambitious programme of construction of fish landing centers with cold chains and aqua shops can lead to better value realization and fishing efficiency. Regular dredging has to be undertaken to maintain and enhance the utility of existing fish landing centres etc. Promotion of mariculture, seaweed culture, fish aggregating devices, artificial reefs, mussel culture are some other untapped areas providing employment opportunities provided technology is disseminated and facilitated and user friendly leasing policies in consultation with stakeholders are put in place. Institutionally, the potential of these initiatives can be optimized through setting up of a separate Department of Fisheries under Ministry of Agriculture, a National Fisheries Development Board to provide technical and infrastructural support to fishers, a Central Fisheries Harbour Development Authority and restructuring of Central Institute of Fisheries Education, Mumbai alongwith setting up of Fish for all training centres for capacity building to provide a fillip for human resource development to all the stakeholders in fisheries.

5. Welfare of fishers can be promoted through a substantial hike in their compensation during close season and an Endowment Scheme for fishers more than 60 years of age. Some 3600 fisher villages should be provided better infrastructure of roads, housing, drinking water,
electricity etc. in view of their precarious living conditions and hazardous occupation. Benefits of Prime Minister’s Bharat Nirman should flow to these villages on priority.

7. Additional requirements of funds up to the end of 11th Plan
   1. Margin money for ICAR Fisheries Institutions  (Para 3.1.1.20.3)  Rs. 30 crore
   2. Fishermen’ Welfare Scheme  (Para 3.1.4.5)  Rs. 350 crore
   3. 10 fish hatcheries  (Para 3.1.11.2)  Rs. 15 crore
   4. 10 Common Infrastructure Support Units
      for shrimp States  (Para 3.1.18.18 )  Rs. 50 crore
   5. 20 composite fish marketing support units  (Para 3.1.24.4.3)  Rs.20 crore
   6. 2 mother ships  (Para 3.2.9.3)  Rs.10 crore
   7. 20 minor fisheries harbours  (Para 3.2.12.3)  Rs.240 crore
   8. 40 fish landing centres  (Para 3.2.12.3)  Rs. 120 crore
   9. 3 small sized Dredgers  (Para 3.2.12.4)  Rs. 30 crore
   10. 34 Village Knowledge Centres  (Para 3.2.18.3)  Rs. 17 crore

   Sub-total:  Rs. 882 crores

Note: A sum of Rs.3500 crores would be needed for the National Fisheries Development Board, consisting of 50% grant and 50% loan, if the Board is set up.
ENHANCING PRODUCTIVITY, PROFITABILITY, STABILITY AND SUSTAINABILITY

CHAPTER 4.1 - HILL AGRO ECOSYSTEM

The hill agro ecosystem represents the vast reservoir of fresh water, biological diversity and niche resources for hydropower and forests. It, however, suffers from inaccessibility, marginality, fragility and higher costs of services and marketing. The development, investment and governance paths adopted in the past have often been divorced from ground realities and local communities.

2. **New Policy: Correcting the Big Mistake:** The National Policy on Agriculture should have a specific, yet integrated, policy on hill agriculture so that commensurate strategies, programmes and activities for hills–plains integration and hill agriculture development geared towards socio-economic and agro ecological synergy could be established. The hillside development policies focusing on forest cover through regulations had wrongly excluded local users across a wide range of ecological and socio-economic regimes. **Inter-disciplinary studies should be undertaken to analyse the cause-effect relationships and to test the old and new approaches to guide future efforts based on scientific facts.** Baskets of eco-technological and knowledge-based options are needed to achieve synergistic enhancement of productivity, profitability and sustainability. A **National Hill Coordinating Centre** to integrate all programmes of the Government of India on Hill Agriculture should be established. The Centre may be Chaired by the Union Minister for Agriculture and closely linked with other concerned Ministries as well as with the National Development Council. A **National Hill Agriculture and Livelihood Development Fund** should be created for judicious implementation of the Hill Policy.

3. While the population growth rate should decelerate, off-farm and non-farm employment opportunities should be created to reduce the pressure on land and other natural resources. The issues of synergy amongst all sub-sectors of agriculture, namely, crops, livestock, fisheries and forestry, inclusiveness, rights and aspiration of all hill people should be specifically addressed. The policy should provide for niche-based high-value farming and income generation, diversification, value addition, market reforms, entrepreneurship development and other
institutional supports. Accurate survey and measurement of area and use patterns of hill/mountain lands should be undertaken to ensure knowledge-based and informed allocation and deployment of natural resources.
4. **Food, Nutrition and Income Security: A Hill Farmers’ Council for Sustainable Food Security** should be established to coordinate and integrate NEGS and FFW and other programmes under the proposed **National Food Guarantee Act**, adopting the whole-life cycle approach. It should promote SHGs to establish and operate **Community Food Banks (CFB)** and promote sustainable enhancement of productivity to further increase the productivity and marketable surpluses, specially of small farmers. The **Land Use Boards** should be restructured to be able to proactively advise farmers, based on congruence of agro-climatic capacity with agro-economic-ecological opportunities and market prospects. Fodder and feed availability should be ensured by promoting integrated management of grazing lands, fodder production and stall feeding, creation of **fodder and feed banks** and by establishing **Livestock Food Corporations**. The underexploited potential of fisheries sub-sector should also be harnessed.

5. **Towards Jal Swaraj : Hydrological Balance  and Water Security**: Two complementary approaches are needed: (a) harvesting of rainwater, groundwater recharge and efficient use of water and (b) the hydrological balance in the Himalayas as dictated by the snow and glacier regimes and climate change. As regards the first component, water harvesting structures, including roof-top water harvesting, and improvement and creation of lift irrigation schemes should be ensured by involving water user associations including PRIs, NGOs and local communities. Pressurised micro irrigation (with assured quality of appliances), rehabilitation of hydrological hot-spots and water bodies, establishment of Low Water Parks, promotion of low water requiring high value crops, popularization of low-cost green houses coupled with fertigation, recharging of dead wells, reviving of the “dying wisdom”, establishment of water banks, creation of skilled manpower and human resources for managing water at various levels and, above all, fostering water literacy so that water becomes everyone’s business, constitute the essential elements of ensuring water security at the household and farm levels.

6. As regards the hydrological balance, a **National Research Centre on Glacierology** should be established for collection, storage and dissemination of information on status of seasonal/perennial snow and ice. The Centre should undertake research on understanding the interaction amongst biological processes, physical environment and the climate change and
develop early, medium and long-term warning systems and advise on trends of water availability and overall hydrological situation in the medium and long-term. Further, an iterative process of **integrated basin management** should be established with clearly defined objectives, planning process, implementation modality and monitoring and evaluation mechanisms, which would help also in accessing the proposed national plan of physically linking all the major rivers of the country.

7. **Soil Health and Bio Diversity Security:** The following sets of actions should be taken towards ensuring soil health and bio diversity security: (i) Correct soil micro nutrient deficiency (**hidden hunger**), adopt IPM and IPNS, issue **soil health card** to each farmer and establish atleast one modern soil testing laboratory in each District for micro-nutrient analysis, and launch a **community land care movement**, (ii) digitize inventory of plant, animal, fish and microbial bio diversity, ensure priority collection of endangered species and prepare and **undertake an integrated collection and conservation programme**, including the establishment of gene sanctuaries, and (iii) undertake niche-production of unique local bioresources and intensify **gene literacy** campaign to enhance participatory conservation and equitable sharing of benefits accruing through the use of genetic resources of specific locations (realization of **Farmers’ Right**).

8. **Reversing the Technology Fatigue:** Each hill State should formulate/update **State Science Policy** to reorient it to be farmer-centred and geared to pursue knowledge-intensive agriculture. **Ecotechnologies** encompassing genetically improved strains, IPM and IPNS should be promoted through **Farmer Participatory Research and Knowledge Management System**. Greater emphasis should be placed on post-harvest management - processing, value-addition, policy and market research, skill development and retooling to strengthen the **production-consumption chain system**. Mandates of the KVKs and ATMAs should be changed to internalize the new developments and priorities in the areas of post harvest management. New extension approaches viz PPP, farmer-to-farmer (**Farm Schools**) etc. should be adopted. Timely and adequate supply of quality seed and other planting materials as well as other inputs should be ensured. **Seed Banks** should be established and preferably operated by SHGs and WSHGs to ensure regular flow of quality materials, particularly under drought and other aberrant weather
conditions. Need-based mechanization of hill agriculture and certification and market-driven and knowledge-based development of organic farming should be streamlined. Following the success story in Uttaranchal, organic villages, covering large number of farmers, should be organized with clearcut outcome in mind.

9. Farmer-centric Market and Institutional Support and Gender Mainstreaming:
Planning for marketing should begin with planning for production. Land Use Boards should have the capacity to advise farmers on market opportunity-based production planning. Given the high marketing costs in hills and to protect farmers’ income, the use of market infrastructures such as warehouses, storages, transport, etc. should be subsidized for the hill farmers. On the other hand, MSP and MIS should be expanded and operationalised also for certain catalytic products from hills. The NHM should give highest priority to value addition, processing, prevention of post-harvest losses and marketing and should adjust its budget allocation accordingly. Separate Regional Master Plans for Market Development in NER and NWR should be prepared, integrating them respectively with SE Asian and West Asian markets.

10. As regards institutional support, credit regulations and packages should be aligned with actual settings in the hills - land rights, jhuming and CPR, and the high costs of services and markets. The Government of India should assist banks in covering the undue risk in hill agriculture and sharpen its life-support assistance to the clearly identified targets. All agricultural development programmes should be engendered. Women must be given land rights and should have access to credit, water, education, health, knowledge and insurance. The indigenous and traditional knowledge uniquely possessed by female farmers should be protected and duly rewarded.

ENHANCING PRODUCTIVITY, PROFITABILITY, STABILITY AND SUSTAINABILITY

CHAPTER 4.2 - ARID AGRO ECOSYSTEMS

Arid agro-ecosystems, receiving less than 450 mm annual rainfall with 40-60% coefficient of variability, covering 31.7 million ha in hot arid and 7 million ha in cold arid zones, account for 12 percent of the geographical area of the country. The arid zones are characterized by permanent water scarcity, intense aridity, fragility of natural resources and recurrent droughts.

2. **Policy Actions for Enhancing and Sustaining Livelihood Security:** The arid region should be separated out for an exclusive policy for drought proofing, land management, survival and livelihood security, and not clubbed together with semi arid regions. **Sustainable Land Management (SLM)**, and not Watershed Development, must be the focus in arid zones. Various ongoing and planned Central and State development programmes in arid agro ecosystems should be coordinated by the proposed MoA-hosted **National Authority for Dryland Farming Areas (NADFA).** A **National Committee on Sustainable Land Management (SLM) in Arid Agro Ecosystem,** under the auspices of the NADFA, with due representation of the cold arid, should be constituted and function as a **multistakeholder consortium.** Arid zone States should constitute State level counterpart Committees.

3. Concerned Ministries and financial institutions should facilitate public-private linkages not only in infrastructure development but also in promotion of rural entrepreneurship and in establishment and strengthening of capacity of PRIs, SHGs, cooperatives, Small Farmers’ Estates (SFEs), etc. to facilitate access to quality inputs and to fair markets. The Central Government should create an **Agriculture-Risk Fund** and design a **special insurance product and dispensation mechanism** to insulate farmers from risks. Fifteen percent of the development budget should be allocated to on-farm strategic research to facilitate generation, refinement and adoption of location-specific technologies.
4. **Livestock, Fodder, Feed, Food and Livelihood Security:** Establish Livestock Food Corporation in each State. The District LSD Consortia should ensure enhanced and sustained production of fodder and feed crops and adoption of recommended livestock management technologies. **Fodder and feed banks** should be established at strategic points. As regards food security, the adoption of proven technologies and development strategies for enhanced productivity, prevention of post harvest losses, value addition and remunerative marketing should be emphasized. **Food, grain, seed and water banks**, preferably operated by SHGs, should be established. The proposed **National Food Guarantee Act** should be operationalised. Off-farm and non-farm employment should be created for increasing income and economic access to food.

5. **Water Security: Conserving Every Drop of Water:** Water literacy should be increased to make water conservation everyone’s business towards more income per drop of water. Rainwater harvesting, restoration of water bodies, reviving of “dying wisdom” and groundwater recharging should be made mandatory to everybody. The various water-related development programmes should be coordinated under one umbrella and synergised at the action site by Panchayats and other grassroots organizations under the direction of the District SLM Consortium. About 10 percent of the total investment in watersheds and soil conservation should be allocated for development and fine-tuning of SLM technologies. Location-specific integrated watershed development programmes and increased water use efficiency particularly through the development and adoption of quality microirrigation, fertigation and low cost greenhouses should be promoted. A **travelling workshop** of experts from India and from the Nile, Jordan and Imperial Valleys should be organized to formulate new strategies for water management.

6. **Soil Health and Technological Security for Sustainability:** Soil-test-based micro nutrient amendments to manage the **hidden hunger** of soil should be widely adopted. Each arid zone district should have at least one well-equipped and suitably staffed advanced soil testing laboratory. Each farmer should be issued a **Soil Health Card.** The **Land Use Boards** should be strengthened to play a proactive role in advising farmers. Selective mechanization should be
supported to enhance precision, timeliness and productivity. **Farm schools** should be established to replicate “bright spots”, particularly IPM, IPNS, and integrated crop-livestock-tree and organic farming technologies. Each KVK should be augmented with a post-harvest technology unit.

7. **Conserving Genetic Heritage and Harnessing Unique Niches:** The national bureaus of plant, animal and microbial genetic resources should chronicle and digitise inventories of the bioresources and associated traditional knowledge, and launch gene literacy movements to sensitise all stakeholders. The Suratgarh Farm (Rajasthan) of the Government of India should be developed as an *ex situ* germplasm repository of arid zone livestock genetic resources.

Production and commercialisation of off-season as well as high value crops and commodities should be strongly supported and promoted. The ICAR should establish a **cold arid regional sub-station at Ladakh** to generate technologies and develop new strategies for capturing the opportunities of the region and should work closely with the proposed National Centre on Glacierology.

9. **Farmer-centred Marketing:** Arid zone farmers should be insulated from price dips in “good” years with timely and effective implementation of MSP and MIS, especially for the life-line commodities. Based on market research, special arid zone commodity markets/parks/zones and periodic markets should be established. Adopting the NDDB model, farmers’ cooperative marketing, fully equipped with grading, sorting, standardization and packaging facilities should be developed. Trade and regulatory policies, including SPS, for dairy products, wool and horticultural and other specialty products should be integrated with the development role of these commodities.

10. **Financial Implications:** An additional sum of Rs. 1,275 crore for the next seven years as detailed below, may be provided in the budget to cater to the above mentioned requirements.

   - Agriculture-Risk Fund ---- Rs.500 crore (GOI)
   - Special Insurance Products and Dispensation --- Rs. 300 crore (GOI)
- Micro-Capital Grant to support drought proofing and to assist and mentor SHGs and SFEs --- Rs. 300 crore (State Governments and GOI)
- Special Market Intervention Scheme --- Rs. 100 crore (GOI)
- Establishment of modern marketing centre --- Rs. 75 crore (GOI)
ENHANCING PRODUCTIVITY, PROFITABILITY, STABILITY AND SUSTAINABILITY

CHAPTER 4.3 - COASTAL ZONE AGRICULTURE

1. Nearly 25% of India’s population lives in coastal areas. Anthropogenic pressures on coastal ecosystems and living aquatic resources are increasing. There is urgent need for sustainable livelihoods and sustained production.

2. We recommend the establishment of **agro-aqua farms** on coastal wastelands under a **National Sea Water Farming for Coastal Area Prosperity Project** in about 50,000 ha in the States of Gujarat (Kutch), Maharashtra, Goa, Karnataka, Kerala, Tamil Nadu, Andhra Pradesh, Orissa and West Bengal, as well as in Andaman and Nicobar and Lakshadweep Islands. **Women’s Aquaculture Estates** should also be established along the coast through Women’s Development Corporations and financial institutions for the purpose of assisting **dalit** and fisherwomen to take to sustainable and profitable aquaculture. The programme based on sound scientific principles of agro-forestry may be given priority in the livelihood rehabilitation programmes being sponsored under the Prime Minister’s Relief Fund in tsunami affected areas.

3. **There is need for a Coastal Systems Research Programme (CSR) on the lines of Farming Systems Research Programme carried out in inland areas.** We recommend that ICAR may initiate an All India Co-ordinated Research Programme on coastal agriculture, jointly with CSIR and State Agricultural / Animal Husbandry / Fisheries Universities.

4. We suggest that a **National Board for Sea Water Farming** be set up under the Chairmanship of Minister for Agriculture and Food. The Board should have the Ministers in charge of Environment and Forests, S & T, Ocean Development, Water Resources and Commerce, and senior representatives from all the Coastal States and Islands, as Members, so that a holistic view on all aspects of seawater use and coastal agriculture management can be taken.
SUGAR INDUSTRY IS THE LARGEST AGRO-BASED INDUSTRY IN RURAL INDIA. THE INDUSTRY HAS ENABLED THE COUNTRY TO BE SELF-RELIANT IN THIS HIGHLY SENSITIVE ESSENTIAL COMMODITY OF MASS CONSUMPTION. INSPITE OF THE FACT THAT SUGAR IS PROBABLY THE MOST DISTORTED AGRICULTURAL PRODUCT IN THE GLOBAL MARKET, INDIA EXPORTED ABOUT 4 MILLION TON OF SUGAR DURING THE LAST THREE YEARS. HOWEVER, THE GROWTH RATES IN CANE CRUSHING CAPACITY, QUANTITY OF CANE CRUSHED AND SUGAR PRODUCTION HAS OUTSTRIPPED THE SAME IN TERMS OF AREA UNDER SUGARCANE, ITS YIELD RATE AND TOTAL PRODUCTION LEADING TO A GENERAL SHORTAGE OF SUGARCANE FOR THE SUGAR FACTORIES. THE STATUTORY MINIMUM PRICE [SMP] OF SUGARCANE [DECLARED BY THE GOVERNMENT OF INDIA] HAS BEEN CONTINUOUSLY INCREASING. BETWEEN 1999-2000 & 2002-03 WHILE THE SUGAR PRICES DECLINED FROM 141.2 [BASE 1993-94] TO 117.1, THE SUGARCANE PRICES INCREASED FROM RS 56.10 PER QTL TO RS 64.50 PER QTL WITH 8.5% BASIC SUGAR RECOVERY. INCIDENTALLY, THE SUGARCANE FARMERS ARE A STRONG FORCE IN THE MAJOR SUGARCANE PRODUCING STATES. THERE ARE PRACTICES REGARDING SUGARCANE AREA RESERVATION, PRICING, PAYMENT FOR SUGARCANE, SUPPLYING ARRANGEMENT AND THE DEVELOPMENTAL ROLE OF THE SUGAR FactORIES, WHICH ARE PEHELAR TO THIS INDUSTRY. WITH THE INCREASE IN POPULATION AND THE ANTICIPATED INCREASE IN PER CAPITA CONSUMPTION OF SUGAR, IT IS ESTIMATED THAT THE DEMAND OF SUGAR WOULD REACH ABOUT 24.5 MILLION TON BY 2010 FROM ABOUT 18 MILLION TON IN 2001-02. WITH THE EXISTING LEVEL OF PRODUCTIVITY AND QUALITY OF SUGARCANE, IT WOULD NEED AN INCREASE IN AREA UNDER SUGARCANE FROM THE EXISTING 4.4 MILLION HECTARE TO ABOUT 5.5 MILLION HECTARE, WHICH MAY BE EXTREMELY DIFFICULT DUE TO CLAIMS OF OTHER CROPS AND LARGE WATER REQUIREMENTS.

2. The all India yield of sugarcane had been nearly stagnant for quite sometime and during the last five years it has continuously declined from 71.2 ton/ha in 1998-99 to 64.6 ton/ha in 2002-03. The need is to introduce packages of improved technology, services and public policies designed to raise productivity and quality of sugarcane crop. It is suggested that a Technical Mission on Sugarcane [TMS] be established jointly with sugarcane growers’ organisations, banks, sugar factories and research organisations on the basis of a ‘seed to sugar’ approach to improve the All India average sugarcane productivity to at least 80 ton/ha and sugar recovery to
at least 11% in five years. India has the technical know how and do how to achieve this. There are huge gaps in yield potential and actual yield. The productivity in the sub-tropical States, which have nearly 60% of the total area under sugarcane, is substantially lower than that in the tropical States. If the levels indicated above were achieved, there would be enough sugarcane to have 25 million ton sugar per year. The TMS could have three major components: (a) Intensification of sugarcane research (b) Transfer of technology (c) Improving productivity and quality of sugarcane

3. The TMS would have to be placed under the exclusive charge of a senior knowledgeable officer of the Government of India to be declared as Mission Director. In the major sugarcane producing provinces, the State Governments may designate State level ‘Mission Director’ to act as ‘nodal officer’. The initial assessment of the cost of the programme for a five-year time slice is Rs 900 crore. However, this would require to be firmed up on a item wise basis. The additional annual production of sugar with increased productivity and quality of sugarcane would be worth about Rs 7000 crore.
Enhancing Productivity, Profitability, Stability and Sustainability

Chapter 4.5 - Conservation, Cultivation and Marketing of Medicinal Plants

Medicinal and aromatic plants provide a window of opportunity to concurrently strengthen health, food, nutrition, and livelihood security of farm families and agro-ecological security of the environment. Traditional systems of medicine have been used in India over the years to address human, animal and plant health. India as one of the biodiversity rich countries with a rich heritage of traditional medicine has the potential to be a leading player in the sector.

Recommendations

2. Immediate measures are needed in the areas of Policy, R&D, Input supply, Market, Pricing Support and Information Portal on MAPs. A National Mission on Medicinal and Aromatic Plants may be organized to ensure that the sector receives the integrated attention it deserves. The recently approved National Horticulture Mission (NHM) includes MAPs, but given the already large number of fruit, vegetable and flower species to be addressed under the NHM, the MAPs may not receive the special attention and leadership it urgently needs. Pending the preparation of a full-fledged Mission, a distinct Mini-Mission may be organized for MAPs under the ongoing NHM. A dynamic leader in the area of medicinal plants and herbal medicine may be appointed as the coordinator of the Mini Mission for MAPs.

3. The Mission should have a Policy Guidance Committee (PGC), an apex level body comprising the Ministers of Agriculture, Health, Environment & Forests, Commerce and Science & Technology, to give direction. The PGC could guide the restructuring of the National Medicinal Plants Board (NMPB) on the lines of NDDB.

4. Measures to ensure supply of quality planting material, research on quality, safety and efficacy of products, standardization of products and suitable regulation, proper pricing for harvested and cultivated produce, a market oriented strategy to guide cultivation for the home
and external markets, documenting and recognition of traditional knowledge on medicinal plants, and setting up a single window information portal are the areas needing immediate attention.

5. Promotion of Public-Private Partnerships (PPP), promotion of Contract farming and appropriate codes of conduct, encouraging different Commodity Boards to promote intercropping with plantation crops, forming Medicinal Plant Growers’ Association, community-based herbal gardens and enterprises and **Herbal Biovalleys** on the model of the Silicon Valley may be nurtured for providing the infrastructure needed for the conservation and sustainable use of medicinal plants.

6. The TF Report on MP had in 2000, recommended an allocation of Rs.1000crore for development the sector. It is recommended that an equivalent amount be made available to the proposed National Mission on MAPs in order to enable it to launch a dynamic programme in the areas of conservation, cultivation, scientific validation, and marketing under distinct brand names.
There is a growing interest in organic farming practices in several parts of India, partly due to an expectation of higher prices for organically produced farm commodities. It will be useful to promote organic farming for low volume, high value crops like spices, medicinal plants, fruits and vegetables. Internationally acceptable certification standards and institutional structures are urgently needed. Cost of certification also has to come down.

2. Preparation of Organic Farming Tool Kits, based on IFOAM principles, to assist farmers on the do’s and don’ts relating to the production of organic farm produce, promoting the formation of Small Farmers’ Organic Agriculture Estates and Organic Farmers’ Clubs to confer the power of scale at the production and post-harvest phases of farming to small farmers, organizing a National Federation of Organic Farmers’ Associations on the pattern of IFOAM, and declaring Organic Farming Zones are some of the steps needed to give direction and support.

4. Organic farming needs even greater research support than chemical farming. Our National Agricultural Research System will have to develop bio-organic farming methodologies.

5. It would be useful to develop a national strategy for organic farming, specifying regions, crops and seasons, ideal for raising crops through organic farming techniques.
ENHANCING PRODUCTIVITY, PROFITABILITY, STABILITY AND SUSTAINABILITY

CHAPTER 4.7- BIOFUELS

Bio-fuels derived from plant-based resources assume importance in the context of the need to develop non-renewable sources of energy. Farmers’ organizations need proper extension advice on the advisability of shifting their land use to the cultivation of crops for bio-fuel production. A well-defined Biofuel policy based on science and economics needs to be developed jointly by the Union Planning Commission, Ministries of Agriculture, Rural Development, Petroleum, Non-Conventional Energy Sources and Science & Technology. ICAR and CSIR will have to be actively associated. The economic and ecological sustainability of this programme should be the bottom line in decision-making.

2. A systems approach is necessary for ensuring that the different components of bio-diesel programme are effectively coordinated and bio-diesel becomes a cost effective alternative. There is need for convergence and synergy in Technology and Public Policy for farmers to undertake farming of crops used in ethanol and other biofuels. Necessary industrial infrastructure should be developed to process the collected biomass for production of ethanol / other biofuels and the by-product industrial wastes so generated, could be used as manure.

3. ICAR and CSIR should jointly undertake to work on developing suitable process development for biofuels from various feedstocks and for developing agronomic practices for growing crops for biofuels in wasteland in cooperation with State Agricultural Universities.

4. It is recommended that a 'National Biofuel Board' headed by the Member in charge of Energy in the Planning Commission, be set up to develop a roadmap for use of biofuels in petrol and diesel engines in a time bound manner. The Board should be supported with appropriate technical and financial resources and function like the Atomic Energy Commission with specific targets, autonomy and accountability.
CHAPTER 5 - AGRICULTURAL MARKET REFORMS

An efficient marketing system is essential for the development of the agricultural sector, providing incentives to the farmers for commercialisation, increasing production and giving appropriate signals for production planning and research activities. At the time of independence, there was shortage of production against demand and the immediate concern was to save the farmers and the consumers from malpractices of traders and facilitate growth and development of an orderly marketing arrangement. Organized marketing of agricultural produce was promoted though regulated markets. The State Governments and the Union Territories passed the APMC Act and in view of the supply side constraints various other legal enactments were promulgated and orders covering specific products issued. The resultant Government monopoly in setting up agricultural produce markets under the State specific Acts virtually prevented the private sector from taking any important initiative in the development of agricultural marketing infrastructure. There is no doubt that a large network of 7418 wholesale agricultural produce markets under the regulated system has been created and there is improvement in marketed surplus-output ratio, standardization of marketing charges, improvement in quality of market information etc but the lack of basic infrastructure, inadequate development of rural periodic markets, lack of transparency in weighing, auctions, other market related matters, sale of ungraded produce, distress sale immediately after harvest, poor quality of services offered to the farmers and lack of professionalism continue to be some of the constraints.

2. The Ministry of Agriculture is playing a proactive role in bringing about a change in the mindset from trade regulation to trade promotion, establishment of rural godowns, warehouses, cold storages and amending the APMC Act by the State Governments/Union Territories with a view to primarily enable the private and cooperative sector to establish and operate markets for agricultural commodities and offer the farmers an alternative. However, the response of some of the State Governments is inadequate. With increasing commercialisation of agriculture, market planning needs to begin before the production planning. The restructured State Land Use Boards supported by a team of technical experts/agencies could render much needed advice to the farmers based on meteorological,
marketing and management information. More storage including cold storage and warehouse capacity should be created and warehouse receipt be developed as an effective credit instrument. There is also a need to encourage setting up of farmers’ markets, development of farmer’s organisations under the banner of the commodity produced by them, develop farmer centric code of conduct for contract farming, improving quality concern among the producers, increasing flow of marketing credit, tightening of the supply chain, minimizing post harvest losses and improving value addition to enhance the farmer’s income.

3. The various legal enactments concerning agricultural processing and marketing particularly the Essential Commodity Act need a revisit.

4. The Minimum Support Price [MSP] is the major instrument of agriculture price policy of the Government of India. There is need for much stronger protection of MSP across the country. The MSP system, which has contributed towards diversification and commercialisation of Indian agriculture and also in achieving the present level of production, needs to be continued in near foreseeable future and its implementation should be improved. Price behaviour of sensitive commodities not covered by MSP, needs to be closely monitored particularly during the glut season for need based support under the Market Intervention Scheme.
COMPOSITE FINANCIAL SUMMARY

Chapter 1: From Crisis to Confidence

1. Beyond Tsunami Agricultural Rehabilitation Demonstration programme
   Funds for the Demonstration cum Training programme may be provided from the Tsunami Relief Allocation at the rate of Rs. 20 lakhs per demonstration, each covering an area of 200 ha. In all about 15 such demonstrations may be organized in the affected states and in Andaman and Nicobar Islands at a cost of Rs. 3.00 crore.
   Rs. 3.00 Crore

2. Indo-US Collaboration in Agronomic Rehabilitation Strategy: Rs.1 crore may be allotted for this collaborative programme from the Prime Minister’s Relief Fund.
   Rs.1.00 Crore

3. Mission 2007: Every Village a Knowledge Centre: We recommend that the Ministries of Rural Development and Panchayati Raj provide Rs. 50 crores each for training and capacity building activities during 2005-06.
   Rs.100.00 Crore

4. The Union Ministry of Agriculture may also provide Rs. 50 crores annually during the next 3 years for content creation and capacity building in the areas of crop and animal husbandry, fisheries, forestry, agro-processing and marketing and for imparting quality trade and genetic literacy.
   Rs.150.00 Crore

5. A total of about Rs.3000 crores of public investment may be needed during the next 3 years for making the ‘Every Village a Knowledge Centre’ concept a reality. We suggest that investment in the VKC programme should come from a variety of government sources including the USO fund and the vast resources being set apart for Bharat Nirman.
   Sub-total: Rs.254.00 Crore
Chapter 2: Food for All

To be worked out

Chapter 3: Fish for All

Additional requirements of funds upto the end of 11th Plan

11. Margin money for ICAR Fisheries Institutions (Para 3.1.1.20.3) Rs. 30 crore
12. Fishermen’ Welfare Scheme (Para 3.1.4.5) Rs. 350 crore
13. 10 fish hatcheries (Para 3.1.11.2) Rs. 15 crore
14. 10 Common Infrastructure Support Units for shrimp States (Para 3.1.18.18) Rs. 50 crore
15. 20 composite fish marketing support units (Para 3.1.24.4.3) Rs. 20 crore
16. 2 mother ships (Para 3.2.9.3) Rs. 10 crore
17. 20 minor fisheries harbours (Para 3.2.12.3) Rs. 240 crore
18. 40 fish landing centres (Para 3.2.12.3) Rs. 120 crore
19. 3 small sized Dredgers (Para 3.2.12.4) Rs. 30 crore
20. 34 Village Knowledge Centres (Para 3.2.18.3) Rs. 17 crore

Sub-total: Rs. 882 crores

Note: A sum of Rs. 3500 crores would be needed for the National Fisheries Development Board, consisting of 50% grant and 50% loan, if the Board is set up.

Enhancing Productivity, Profitability, Stability and Sustainability

Chapter 4.1: Hill Agro-Ecosystem

1. Water conservation tanks with and without distribution attachments Rs. 356 crore
2. Micro-irrigation, repair of degraded irrigation systems, expansion of lift irrigation, machines and implements for agricultural mechanisation Rs. 300 crore
3. National Centre on Glacierology Rs. 50 crore
4. Special credit and insurance products, transport subsidy Rs. 500 crore
5. Market Infrastructure development Rs. 300 crore
6. Organic farming certification, model organic villages and marketing Rs. 250 crore
7. Capacity building, training, strengthening and mentoring of SHGs, SFEs, etc; Soil Testing Laboratories Rs. 500 crore

Sub-total: Rs. 2256 crore

Chapter 4.2: Arid Agro-Ecosystem

Part A

1. Agriculture-Risk Fund Rs.500 crore (GOI)
2. Special Insurance Products and Dispensation Rs. 300 crore (GOI)
3. Micro-Capital Grant to support drought proofing and to assist and mentor SHGs and SFEs Rs. 300 crore (SG and GOI)*
4. Special Market Intervention Scheme Rs. 100 crore (GOI)
5. Establishment of modern marketing centre Rs. 75 crore (GOI)

Sub Total A Rs 1275 crore

* Rs.200 crore by the State Government (SG) and Rs. 100 crore by GOI

Part B

1. Contingency fund Rs. 500 crore (GOI)
2. Strengthening horticulture-led diversification Rs. 300 crore (NHM)
3. Livestock ex situ germplasm conservation at Suratgarh Farm Rs. 100 crore (ICAR)
4. Augmenting water availability by promoting rainwater harvesting, groundwater recharge and water bodies restoration, development and management Rs. 250 crore
5. Large scale demonstrations, establishment of fodder, feed and grain banks, Farm Schools Rs. 300 crore
6. Soil health care based on soil test, including micronutrients analysis and popularization of agricultural machines and implements
Rs. 200 crore

7. Commercialization of date palm production, support to micro-irrigation, supply of quality vitroplants and other planting materials
Rs. 120 crore

**Sub-total B Rs. 1770 crore**

**A sum of Rs. 1770 crore is to be met through redeployment of resources from existing National Horticulture Mission and other National Missions, Watershed Projects, ATMA, ICAR’s KVK and other projects and by using the National Rural Employment Guarantee Scheme and the Food for Work Programme.**

**Chapter 4.3 : Coastal Zone Agriculture**

To be worked out

**Chapter 4.4 : Mission for the Prosperity of Sugarcane Farmers**

Rough assessment of the outlay for the project [5 year time slice] is about Rs 900 crore as under.

1. Intensification of research: establishing a sugarcane breeding centre, strengthening of the molecular biology and genetic engineering capacities and other research work.
Rs. 125 to 150 crore

2. Technology Transfer including the seed multiplication programme and maintenance of nucleus seeds and extension work.
Rs. 600 crore

3. Improving productivity of sugarcane: supporting establishment of Soil Testing XXXII
Laboratories, Tissue Culture Laboratories, Bio-fertilizer units and service charges to NABARD

<table>
<thead>
<tr>
<th></th>
<th>Rs. 160 crore</th>
</tr>
</thead>
</table>

Sub-total: Rs. 900 crore

**Chapter 4.5 : Conservation, Cultivation and Marketing of Medicinal Plants**

1. It is recommended that **Rs.1000 crore** be made available to the proposed National Mission on MAPs in order to enable it to launch a dynamic programme in the areas of conservation, cultivation, scientific validation, and marketing under distinct brand names.

   **Rs. 1000.00 Crore**

   Sub-total: **Rs. 1000.00 Crore**

**Chapter 4.6 : Organic Farming**

To be worked out

**Chapter 4.7 : Bio-fuels**

To be worked out

**Chapter 5 : Agricultural Market Reforms**

1. No specific recommendation with additional financial implication made. However, the inter-ministerial task force on Agricultural Marketing [May, 2002] has estimated investment requirements for development of marketing, storage, cold-storage infrastructure during the Xth Plan at **Rs. 12,230 crore**.

   **Grand Total:** **Rs.8337.00 Crore**
Immediate Steps needed to prevent farmers’ suicides:

1  **Credit supply and reform:**
   - There should be a corpus (on the line of calamity funds) for assisting farmers affected by crop losses.
   - Rate of interest may be reduced to 4% simple with government support, instead of compound rate of interest for arrears.
   - Interest on loans in areas hit by drought and floods and for crops under heavy pest infestation, needs to be waived.
   - Introduce a moratorium on debt recovery, including loans from non-institutional sources, till reasonable profit margins are recorded; stagger debt recovery in easy installments
   - Credit should also be available if the farmer is adopting sustainable farming practices including the upkeep of traditional breeds of cattle. NABARD could develop a suitable project for low external input sustainable agriculture and aquaculture (LEISA).

2  **Irrigation and Cropping Pattern:** Regulate cultivation of water intensive cash crops in “dark and grey zones”. Agronomists should present their data not just on the basis of productivity per hectare but on the basis of net income per unit of water.

3  **Inputs:** Introduce appropriate legislation to regulate and deter the sale of spurious seeds and chemicals; promote community-based and managed seed production and marketing units at the village level; promote integrated pest management and integrated plant nutrient management systems.
Agriculture Marketing and Prices: Implement MSP for coarse cereals and pulses; Create a corpus for stabilizing price fluctuations; Introduce quantitative restrictions on imports of farm commodities which constitute the backbone of the livelihood security system in dry farming areas.

Introduce a Farmers’ Livelihood Security Compact to address the above

- **State level Farmers’ Commission** could be set up for the purpose of ensuring dynamic government response to farmers’ problems.
- **Initiate a Census of Suicides** to have a proper understanding, assessment of reasons and count of suicides.
- **Debt survey**: An All India Debt Survey should be undertaken, taking into account newer forms of credit and indebtedness and newer forms of bondage.
- **Debt waiver**: The amount that is to be the cut-off point could be worked out in consultation with Panchayats and farmers’ representatives in the distress hotspot areas.
- **Insurance revival**: There are provisions in the insurance laws that allow LIC to revive the lapsed policies, which should be done in the distress hotspots.
- **Revising import policies**: Prevent inferior quality pepper from entering the state from Sri Lanka. Re-examine and revise import duty on cotton.
- **Market Support**: There is also need for introducing focused Market Intervention Schemes (MIS) in the case of life-saving crops such as cumin in arid areas.
- **Extension work**: Agricultural and Animal Sciences Universities could form Hope Generation Teams (like NSS) of young male and female students who could stay in the distress villages during vacations and extend both technical and psychological support. The universities must be accountable to the farming community and not to private interests.
- **Basic services**: There is urgent need for both affordable health insurance, as recommended in the first report of NCF and the revitalization of primary health care centres.
• **Knowledge Empowerment:** Village Knowledge Centres (VKCs) should be established in the farmers’ distress hotspots. These VKCs could be linked to a Block level Village Resource Centre (VRC) with the help of the Indian Space Research Organisation (ISRO).

• **Enlarging the export of farm commodities:** The Ministry of Agriculture and ICAR should evolve a policy for ensuring that the appellation basmati is used only for traditional fine grain aromatic rices of great antiquity and of a specific geographic origin.

• Initiate Beyond Tsunami Agricultural Rehabilitation Demonstration programme and give approval for the **Indo-US Collaboration in Agronomic Rehabilitation Strategy in Tsunami affected areas**

**Mission 2007 – Every Village a Knowledge Centre**

**Action Point 1:** The Government of India should include in the **Bharat Nirman programme** the establishment of Village Knowledge Centres (VKCs) in each of the about 237,000 Panchayats in the country and in the local bodies in the North East region.

**Action Point 2:** There is need for convergence and synergy among the numerous initiatives of Central and State Governments in the area of ICT for governance and development

**Action Point 3: Connectivity and Content: National Digital Gateways:** A Connectivity and Content Consortia involving all relevant government, academic and private sector institutions need to be set up in every district of the country.

**Action Point 4: Capacity Building:** The Jamsetji Tata National Virtual Academy for Rural Prosperity could be developed as the umbrella organization for capacity building. A **Consortium of Capacity Building Institutions** will have to be organized for each language of communication.

**Until 2010, the aim should be the knowledge and skill empowerment of rural women and men with public funds.**

The process of obtaining the RSP license should be simple and transparent. We recommend that the Ministries of Agriculture, Rural Development, Panchayati Raj, Communication and
Information Technology and Home may jointly develop a simple set of procedures for RSP license.

**Change in Mindset with reference to the role of the Ministry of Agriculture, Government of India**

Several farmers’ organizations have suggested that the Ministry of Agriculture should be renamed as **Ministry of Agriculture and Farmers’ Welfare**. We recommend the serious consideration of this suggestion since farmers’ well-being should be the main goal of the Ministry. This will also help to link faces with figures.

**NDC Committee on Agriculture:** We are happy that a NDC Committee on Agriculture has been set-up under the Chairmanship of Shri Sharad Pawar. We request that the suggestions contained in this Report as well as the earlier one may kindly be examined by the NDC Committee so that appropriate action can be taken concurrently at the Central and State levels.

**CHAPTER 2 : FOOD FOR ALL**

1. **Access to PDS:** People should be able to access grains from PDS whenever they want, wherever they want and in any quantity they want, subject to a few ground rules which will prevent purchase for hoarding and subsequent sale at high prices. That is, flexibility with regard to time of purchase, place of purchase and quantity of purchase needs to be fitted in to the Public Distribution System.

3. Set up **50 SHG capacity building and mentoring centers** in every State, to enhance the management and marketing capacities of members of the Self-help Groups (SHGs).
Such centers can be established in existing institutions like Agricultural, Rural and Women’s Universities, IITs, institutions operated by NGOs, etc.

CHAPTER 3 : FISH FOR ALL

1. State Fishery Department should have exclusive control over stocking, management, leasing, exploitation and conservation of fisheries resources in reservoirs in consultation with Irrigation Department and stakeholders. (Para 3.1.4.2)

2. Fishermen’ Welfare Scheme needs enlargement particularly in terms of size of assistance through frequent consultations with stakeholders. (Para 3.1.4.5)

3. Wetlands should be developed by adopting appropriate policies for stocking of various species of find and shellfishes. This should be done after removal of weeds etc. through Food and Work/ Employment Guarantee Programme. Village Panchayats may undertake this activity in a time bound manner. (Para 3.1.5.1)

4. Sport fisheries and tourism in the hill areas should be encouraged through large scale seed production and stocking of golden mahseer and rainbow trout. (Para 3.1.7.2)

5. The different species of exotic trout (Rainbow/ Brown/ Brook) and indigenous varieties like snow trout should be stocked in the streams in medium and higher altitudes. In lakes and other static water bodies, mirror carp should be stocked through provision of seed and other assistance in order to provide livelihood opportunities to the people living in the hills. (Para 3.1.7.4)

6. National agency for providing HRD support and training to fishers/ aquaculturists/ entrepreneurs/ corporate sector should be set up by restructuring and revitalizing Central Institute of Fisheries Education, Mumbai. (Para 3.1.9)

7. Integrated fish farming in paddy fields and in conjunction with the piggery/ poultry/ duckery should be encouraged through special incentives and by extension agencies/village knowledge centres, especially in the hilly and tribal areas. (Para 3.1.9.5)

8. A professionally managed National Fisheries Development Board should be set up on the pattern of NDDB. (Para 3.1.11)
9. Exotic species such as arctic char and lake trout should be imported for introduction in upland waters in order to provide income opportunity to people in the higher altitudes. Their impact on native biodiversity will have to be monitored. (Para 3.1.12.2)

10. Air breathing fishes should be stocked in shallow, seasonal and weed choked waters, due to the high medicinal value and consumer preference of these species. Their propagation should be encouraged through provision of good quality brood stock to seed farms and through better extension of the technology for their breeding and rearing. (Para 3.1.13.1)

11. Ornamental fish should be further encouraged in view of their export potential and in view of their amenability for production by women in villages as a Cottage industry. This could be through introduction of highly prized varieties and technology dissemination through Village Knowledge Centres. (Para 3.1.14.1)

12. Fish production as a source of family nutrition should be started as a mass movement through promotion of backyard fish farming involving air breathing species such as magur etc., Village Panchayats, Extension Agencies and Village Knowledge Centres must disseminate the required information. (Para 3.1.15.1)

13. Shrimp farming must be further encouraged for global competition by reducing import duties on feed and feed ingredients, reduction in power tariff to bring it at par with Agriculture for small and marginal farmers etc. Fisheries should be treated at par with Agriculture for the purpose of loan on differential rate interest, loan for tube well, power, water rates and income tax as well as assistance for seed/feed/transport. Above all reasonable rates for insurance must be ensured. (Para 3.1.18.5)

14. There should be a national agency to ensure seed certification to ensure quality seed. There should be a registration of all hatcheries in the States and regular inspection of their brood stock and hatching practices. (Para 3.1.18.7)

15. Aquaculture Service Centres/Aqua shops should be set up with laboratory/storage/communication. (Para 3.1.18.8)

16. States Govt. should set up common effluent treatment plants, water testing and disease control laboratory and another infrastructure facilities for shrimp farm clusters. (Para 3.1.18.17)
17. Similarly, an accreditation Cell should be set up to control the quality of feed based on various parameters worked out in consultation with stakeholders and scientists. (Para 3.1.21.3)

18. Department of Animal Husbandry, Dairying and Fisheries (DAHDF) should set up a technical group to develop internationally accepted protocols, which are desirable and feasible for encouragement of organic fish farming in consultation with stakeholders (Para 3.1.23.1)

19. Considering the critical importance of small cold chains in a tropical country like India. Ice plants in the private sector should be encouraged through reduce power tariff, easy availability of credit from Banks, and other operational facilities, which would ultimately result in higher value realization by the fishers. (Para 3.1.24.2.1)

20. Large assembly/auction markets should be designed by Central Institute of Fishery Technology/National Institute of Agricultural Marketing and constructed all over the country by the States with Central assistance to reduce spoilage of fish and promote marketing of fish in hygienic environment. This would encourage greater competition and, therefore, higher prices for fishers. Institutional finance should also be attracted for the purpose. (Para 3.1.24.4.3)

21. States must encourage local bodies to set up hygienic retail fish market in all medium and large towns in the interest of the consumers as well as women who generally market the fish. They could be provided specific grants to work as seed money for drawing institutional finance. Meanwhile Municipal Committees must strictly enforce existing laws for hygienic retailing of fish. (Para 3.1.24.4.4 and 3.1.24.4.6)

22. Women and men who market fish should be provided insulated fish boxes fitted on cycles for mobile marketing of fish to reduce spoilage. (Para 3.1.26.8)

23. There is a need for comprehensive and cohesive set of Aquarian Reforms in order to foster a sustainable and equitable use of both Coastal and inland waters for capture and culture fisheries. (Para 3.1.27.1)

24. A Committee may be set up to prepare proposals for Aquarian Reforms on the lines of land reforms. (Para 3.1.27.2)
25. ICAR centres for the North-East in Barapani should undertake a major programme of seed and brood stock production for species suitable for the North-East, particularly ornamental fish. (Para 3.1.28.7)

26. A coordination council consisting of coastal states and Govt. of India should be set up to review issues relating to better exploitation of EEZ. (Para 3.2.3.1)

27. States should be assisted by Govt. of India to amend their Marine Fishing Regulation Act in a time bound manner, in tune with the latest developments in sustainable utilization of marine fisheries resources. (Para 3.2.4.2)

28. Juvenile harvest should be reduced to the maximum possible extent by introduction of appropriate fishing gear including regulation of cod end net size in line with the technology from CIFT. (Para 3.2.4.5)

29. Restriction in area for resource specific fishing, prolonged seasonal closure for conservation, protection of juvenile and spawners during breeding season should be enforced more strictly by the states in consultation with the stakeholders. (Para 3.2.4.8)

30. Small trawlers should be encouraged through incentives to fish further off shore. (Para 3.2.4.10)

31. Pelagic and mid water trawling should be encouraged through incentives. (Para 3.2.4.11)

32. Research and development efforts should be aimed at developing fuel-efficient fishing craft/gear/methods as well as energy efficient hull designs. (Para 3.2.4.12)

33. Remote sensing for dissemination of information on potential fishing grounds should be undertaken more effectively through provision of communication facilities that can provide real-time information to the small-scale fishing sector. (Para 3.2.5.1)

34. Regular stakeholders consultation should be held to discuss new policy initiatives and constrains. (Para 3.2.6.2)

35. Introduction of resource specific vessels for long lining, purse seining and squid jigging should be taken up on top priority. Mechanized vessels below 20 m. length need major improvements in design for longer voyages. (Para 3.2.8.4)

36. Modern fishing vessels of 15-19 m. OAL are needed to exploit areas between 90-150 m. depths. (Para 3.2.8.4)
37. Mother vessels for on board processing and with refrigerated holds should be introduced to permit longer voyages by fishers. (Para 3.2.9.3)

38. A time bound programme should be undertaken to improve the hygiene and infrastructure facilities at the fish landing centres and fishing harbours including establishment of Aqua shops etc. (Para 3.2.12.2)

39. New minor fishery harbours and fish landing centres should be constructed in accordance with the Master Plan to comfortably accommodate the boats in operation and also ensure hygiene standards particularly for exports. (Para 3.2.12.3)

40. A Central Fishery Harbour Development Authority for composite planning and efficient management of all fish harbours and landing centres should be set up. (Para 3.2.12.6)

41. States must liberalize their leasing polices for promoting mariculture. (Para 3.2.13.2)

42. An All India Coordinated Research Project on Mariculture should be set up for transfer of technology and demonstration to tap the eminence opportunity available in the coastal area for mariculture. (Para 3.2.13.3)

43. States must also formulate/liberalize leasing policies to encourage establishment and the use of Artificial Fish Habitats (AHD) for higher yield of oceanic tuna and Artificial Reefs to provide shelter to fish for breeding and feeding etc. (Para 3.2.15.1 and 3.2.15.2)

44. An All India Master Plan for HRD should be prepared and Fish for All training centres on the pattern of KVKs should be set up for capacity building of fishers. (Para 3.2.18.2)

45. A comprehensive legislation to regulate Indian Fishing Vessels in our EEZ should be promulgated. It should prohibit transfer of catch on high seas and provide further catch to be unloaded only on Indian soil where sufficient spare capacity exists for processing. (Para 3.2.19.1)

46. A separate Department of Fisheries under the Ministry of Agriculture should be set up in the Government of India. (Para 3.2.21.1)

47. State wise Fresh Water Aquaculture Development Plan prepared by CIFA, Bhubaneswar under ICAR, should be discussed with concerned states by DAHDF to identify constraints and ensure speedy implementation with appropriate inputs. (Para 3.2.22.1)
1. A National Hill Coordinating Centre should be established to integrate all programmes of the Govt. of India on Hill Agriculture. The Centre may be chaired by the Union Minister for Agriculture and closely linked with other concerned Ministries and the National Development Council.

2. A National Hill Agriculture and Livelihood Development Fund should be created for judicious implementation of Hill Policy.

3. The existing North Eastern Council and Western Ghat, Eastern Ghat and Deccan Plateau Development Programmes should be overhauled.

4. A Hill Farmers’ Council for Sustainable Food Security should be established to coordinate various ongoing programmes related to food security.

5. The Land Use Boards should be restructured to be able to advise farmers on agro-economical, ecological and market opportunities.

6. A National Research Centre on Glacierology should be established for collection, storage and dissemination of information on status of seasonal/perennial snow and ice and for research leading to systems for early, medium and long term warnings.

7. Implement the recommendations of the Swaminathan Committee recently made for strengthening R&TD and human resources development and deployment in NER.

8. The National Horticulture Mission should allocate adequate funds to hill States to establish mother nurseries and progeny orchards of identified varieties. It should give highest priority to value addition, processing, prevention of post-harvest losses and marketing.

9. Seed Banks should be established and preferably operated by SHGs and WSHGs to ensure regular flow of quality planting material.

10. Separate Regional Master Plans for Market Development in NER and NWR should be prepared.

11. GOI should assist banks to cover undue risk in hill agriculture.
12. All agricultural development programmes should be engendered. The indigenous and traditional knowledge uniquely held by female farmers of the hills not only should be protected but also duly rewarded.

CHAPTER 4.2: ARID AGRO-ECOSYSTEMS

1. Arid region be separated from semi arid regions of the country for an exclusive policy for drought proofing, land management and livelihood security.

2. Various ongoing Central and State Plans in the region should be coordinated by the proposed MoA-hosted National Authority for Dryland Farming Areas (NADFA). A National Committee on Sustainable Land Management (SLM) in Arid Agro Ecosystem under NADFA should be constituted to monitor the outcome of various programmes in the region.

3. Arid Zone States should constitute State level Committees, which conjointly with the National Committee should ensure timely flow of the earmarked funds through the District Sustainable Land Management Consortium to Panchayati Raj Institutions.

4. During the next seven years, both Central and State Governments should at least double their investments in arid zones in particular and fifteen percent of the development budget should be allocated to on-farm strategic research.

5. Fodder, feed, food, grain, seed and water banks should be established at strategic points and preferably operated by SHGs.

6. Various water-related development programmes should be coordinated under one umbrella and synergised under the District SLM Consortium.

7. Each KVK should be augmented with a post-harvest technology unit and may be redesignated as Krishi and Udyog Vigyan Kendra (KUVK).

8. Suratgarh Farm (Rajasthan) should be developed as an *ex situ* arid zone livestock germplasm repository.

9. The ICAR should establish a cold arid regional sub-station at Ladakh to generate technologies and develop new strategies for capturing the opportunities of the region.
CHAPTER 4.3: COASTAL ZONE AGRICULTURE

1. Initiate Programme on “Sea Water Farming for Coastal Area Prosperity: Establishment of agro-aqua farms in about 50,000 ha in the States of Gujarat (Kutch), Maharashtra, Goa, Karnataka, Kerala, Tamil Nadu, Andhra Pradesh, Orissa and West Bengal, as well as in Andaman and Nicobar and Lakshadweep Islands. Coastal wastelands could be identified for this purpose.

2. Establish Women’s Aquaculture Estates along the coast through Women’s Development Corporations and financial institutions for the purpose of assisting dalit and fisherwomen to take to sustainable and profitable aquaculture.

3. There is need for a Coastal Systems Research Programme (CSR) on the lines of Farming Systems Research Programme carried out in inland areas. We recommend that ICAR may initiate an All India Co-ordinated Research Programme on coastal agriculture jointly with CSIR.

4. A National Board for Sea Water Farming (agriculture will cover crop and animal husbandry, fisheries, forestry and agro-forestry) may be set up under the Chairmanship of Minister for Agriculture and Food with the Ministers in charge of Environment and Forests, Science & Technology, Ocean Development, Water Resources and Commerce and senior representatives from all the Coastal States and Andaman & Nicobar and Lakshadweep Islands as Members.

CHAPTER 4.4: MISSION FOR THE PROSPERITY OF SUGARCANE FARMERS

1. A Technology Mission on Sugarcane (TMS) is suggested for 5 years for improving the productivity and quality of sugarcane so as to have enough sugarcane to produce annually 25 million ton of sugar without any increase in the area under the crop.
2. The TMS may be placed under the exclusive charge of a senior officer of the Govt. of India to be designated as ‘Mission Director’.

3. In the major sugarcane producing States, the Governments may designate a State level ‘Mission Director’ to act as ‘nodal officer’.

4. A High Level Committee of 15 members with representatives from the Government of India, States Government [on rotational basis] banks [rotational basis] Research Institutions, NABARD, RBI, Industry and Farmers under the Chairmanship of the Hon’ble Union Agriculture Minister to oversee the programme.

5. Similar Committees in the ten major sugarcane producing States be constituted.

CHAPTER 4.5: CONSERVATION, CULTIVATION AND MARKETING OF MEDICINAL PLANTS

1. Set up National Mission on Medicinal and Aromatic Plants. To start with, it maybe a Mini Mission under the National Horticulture Mission. The Mission should have a Policy Guidance Committee (PGC), an apex level body comprising the Ministers of Agriculture, Health, Environment & Forests, Commerce and Science & Technology, to give direction. The PGC could guide the restructuring of the National Medicinal Plants Board (NMPB) on the lines of NDDB.

2. Medicinal Plants Growers’ Associations each covering about 100 ha could be formed on the model of SHGs

3. Pricing: The Commission on Agricultural Costs and Prices (CACP) of the Ministry of Agriculture, in close consultation with the Ministry of Environment and Forests, and Department of AYUSH of the Ministry of Health, particularly the NMPB, and Ministry of Commerce, should address the problem of pricing.

4. Herbal Biovalleys may be developed on the model of the Silicon Valley for providing the infrastructure needed for the conservation and sustainable use of medicinal plants. A Project Design Team may be immediately constituted with members drawn from the
NMPB, NBDB, NHM, NABARD and APEDA, to prepare a Business Plan for the world’s first Herbal Biovalley in Kerala as recommended by the Kerala Commission on WTO Concerns in Agriculture, and at other suitable locations in Western and Eastern Ghats, and western, central, eastern, Himalayas and in the N E Region.

CHAPTER 4.6: ORGANIC FARMING

1. Promote formation of Small Farmers’ **Organic Agriculture Estates and Organic Farmers’ Clubs**

2. Organize a **National Federation of Organic Farmers’ Associations** on the pattern of IFOAM.

3. **Organic Farming Zones** can be promoted under the National Horticulture Mission for fruits, vegetables, tea, spices and medicinal plants, so that certification and quality control become easy.

4. Develop a national strategy for organic farming, specifying regions, crops and seasons, ideal for raising crops through organic farming techniques.

CHAPTER 4.7: BIO-FUELS

1. A well-defined **Biofuel policy** based on science and economics needs to be developed jointly by the Union Planning Commission, Ministries of Agriculture, Rural Development, Petroleum, Non-Conventional Energy Sources and Science & Technology. ICAR and CSIR will have to be actively associated.

2. **Set up a National Biofuel Board.** The Board may have the following composition:
   - Chairperson : An eminent professional in the area of biofuels
   - Members : Member (Agriculture) incharge of feedstock production
   - Member (Processing and quality control)
   - Member (Marketing, industry-farmer linkages through contract purchase etc.)
   - Member (Centre – State coordination, linkages with private sector, global technology watch)
A Board of the above kind may function like the Atomic Energy Commission with specific targets, autonomy and accountability.

CHAPTER 5: AGRICULTURAL MARKET REFORMS

1. The APMC Act in different States/Union Territories needs to be amended on the lines of the draft of the amended. APMC Act circulated by the Government of India. It would encourage private sector investment in development of agricultural marketing.

2. Need for review of the Essential Commodity Act and other Acts/Orders concerning storing, marketing and processing etc of the agricultural commodities.

3. Improve the marketing infrastructure and bring about more transparency in auction and other marketing related matters in the regulated matters.

4. The role of the Agricultural Produce Marketing Committees and the State Agricultural Marketing Boards to change from regulation to development and promotion of markets for the local products and better marketing practices.

5. Restructure the Land Use Boards and provide technical support to then to give pro-active advice to the farmers based on meteorological, marketing and managerial information on matters concerning choice of crops/varieties/timing/marketing etc.

6. Establish commodity based farmer’s organisation to develop market orientation among the farmers and articulate farmer’s issues on commodity basis.

7. Develop a farmer centric ‘Code of Conduct’ for contract farming and encourage farmer’s groups/organisations to deal with the purchaser/processor.

Reduce the post harvest losses by training, development of appropriate equipments, facilities and also tightening of the supply chain. Encourage farmer’s groups/cooperative societies to involve in marketing of agricultural produce.
CHAPTER 1
FROM CRISIS TO CONFIDENCE

1.1.0 The Setting

1.1.1 The first report of the NCF was presented to the Government in December 2004. We are indebted to the Government of India as well as to several State Governments for taking prompt action on some of our recommendations. The Union Planning Commission has made an in-depth appraisal of the progress made in agriculture and allied sectors as part of the Mid-term appraisal of Tenth Five Year Plan (2002-2007). The findings were discussed at the 51st meeting of the National Development Council (NDC) on 27-28 June, 2005. It will be appropriate to begin this second report of NCF with a few quotations from the points made by the Prime Minister, the Union Minister for Agriculture and the Deputy Chairman of the Union Planning Commission at the NDC meeting.

1.2.0 Points made at the NDC meeting

Dr. Manmohan Singh, Prime Minister:

1.2.1 “A particularly disturbing aspect of our performance over the past several years is that agricultural growth has decelerated after the mid-1990’s. Agriculture had grown at 3.2% from 1980 to 1996. It decelerated to 2.1% during the Ninth Plan. The cornerstone of the Tenth Plan strategy was a reversal of the declining trend in the growth rate of agriculture and with a target for agricultural growth at 4%. Unfortunately, actual performance of agriculture appears to have deteriorated even further and will possibly not exceed 1.5% during the first 3 years of the Plan…… Correcting this must be accorded the highest priority……. We must have the ambition to double our agricultural production in ten years.”

1.2.2 Shri. Sharad Pawar, Union Minister of Agriculture, Food & Civil Supplies, Consumer Affairs and Public Distribution:

“The tragic incidents of farmers’ suicides in some of the States have been a matter of serious concern……. crop losses, consecutive failure of monsoon, recurrent
droughts, mounting debts, monocropping, land tenancy, etc., seem to be some of the main causes…… 76% of the victims were dependant on rainfed agriculture and 78% were small and marginal farmers…… 76% and 82% of the victim households had borrowed from non-institutional sources in 2000-01 and 2002-03 respectively. The interest rates charged on such debts ranged from 24 to 36%, as compared to 9-12% on institutional credit.”

1.2.3 “The livestock sector is extremely important for providing supplemental income to the farmers. Studies have shown that farmers’ suicide is practically non-existant in areas where the farmers have opportunity to earn income by activities like dairying……. But the fact remains that our cattle productivity is one of the lowest in the world.”

1.2.4 “Agriculture sector is covered in the State List of the Seventh Schedule to the Constitution. Hence, it is the primary responsibility of the State Governments to develop and promote agriculture and increase its production and productivity….. The share of agriculture and allied activities in the total allocation of all State/ UTs taken together is a meagre 6.46% for the Tenth Five Year Plan and 5.62% for the Annual Plan of 2003-04.”

1.2.5 Dr. Montek Singh Ahluwalia, Deputy Chairman, Planning Commission:

“Agricultural growth has decelerated from 3.2% in the period 1980-81 to 1995-96 to an average of below 2% subsequently….. Employment generation in the economy is not upto expectations. Organised sector employment has fallen in absolute terms in the last three years……. The situation regarding groundwater use is also very disturbing. There is excessive drawal of groundwater leading to an alarming lowering of the water table in many areas….. Rainfed areas account for two-thirds of the cultivable area at present and it is necessary to develop a coherent strategy for water conservation and management for these areas.”

1.2.6 Thus, our agriculture is in a state of crisis. The rate of growth in food production has fallen below population growth rate. To achieve a 4% growth rate in agriculture, we must aim at a 8% growth rate in horticulture and animal husbandry. How are we going to achieve these goals? This calls for a higher investment in irrigation, animal husbandry, fisheries, post-harvest technology, rural energy supply and communication. The investment in agriculture has stagnated at 1.3% of GNP during the last three Five Year Plans.
1.3.0 The Agrarian Crisis: Remedies

1.3.1 The Prime Minister and Minister for Agriculture and Food have both suggested several measures to overcome the agrarian crisis. The Prime Minister has emphasized the need for increasing investments in the entire chain of activities related to agriculture and for promoting water efficient technologies. He has called for a sharper focus on strategic research and extension for overcoming the current technology fatigue.

1.3.2 The Agriculture and Food Minister has advocated a greater focus on the development of marketing infrastructure and the introduction of marketing laws conducive to direct marketing and contract farming. He has also pleaded for making the National Horticulture Mission which has a Plan outlay of Rs. 2300 crores during the remaining part of the Tenth Plan period, a success.

1.3.3 The agricultural crisis should be viewed not just in terms of growth rates. If we place faces behind figures, over 400 million children, women and men belonging to families with small and marginal holdings, as well as landless labour families, are in deep distress. This explains why we are off-track in achieving the UN Millennium Development Goals in the areas of reducing poverty induced hunger or under-nutrition, infant and maternal mortality rates and control of major diseases (Table - 1). According to a survey carried out by NSSO, on behalf of the Ministry of Agriculture, 40% of the 51,770 farm households surveyed said that they would quit agriculture, given a chance. No wonder, the mass media have started focusing attention on hunger and farmers’ distress hotspots. For example, the July 4, 2005 issue of a national magazine (Outlook) contains a cover page article on “The death of the Indian Farmer”, to highlight the fact that “trapped in a vicious cycle of crop failure, high debt and penury, the Indian farmers’ future is an endless night.”

### 1.4.0 From Crisis to Confidence

1.4.1 How can we once again generate confidence in our agricultural capability? How can we convert despair into hope in farmers’ homes? Several solutions had been
offered in our first report and it may be appropriate to reiterate their importance
and urgency, since they are yet to be implemented. We cannot afford to relax in the
field of agriculture, since apart from its deep human and livelihood implications,
agricultural decline will erode national sovereignty in the area of foreign policy.
Accelerated agricultural progress will confer multiple benefits – nutritional, economic,
ecological, social and political.

1.4.2 Under WTO regulations, extending essential and life-saving services to resource
poor farmers will not be considered trade distorting. The following steps, recommended
in our first report, need to be implemented without further delay:

i) **Water for Agriculture:**
Implement a Million Wells Recharge programme, make water harvesting
mandatory and restore water bodies.

ii) **Soil Health Enhancement:**
Establish a **Network of advanced soil testing laboratories** capable of testing
large numbers of soil samples for 16 macro and micronutrients and issue a **Soil
Health Card** to every farm family. Remove the hidden hunger of soils by
providing the necessary micro-nutrients. Micro-nutrient deficiencies are
widespread in all our soil types and as a single step, the amelioration of soil
hunger makes the largest contribution to productivity improvement.

iii) **Bridging the widening gap between scientific know-how and field level
do-how:**
Establish without any further delay about 50,000 Farm Schools for the purpose of
farmer-to-farmer learning. The Farm Schools should be established in the fields of
farmer achievers who are actually enhancing productivity and profitability in
their farms through scientific and sustainable agriculture. Priority may be given in
the areas of horticulture, crop-livestock, mixed farming, organic farming, agro-
forestry and aquaculture for establishing Farm Schools. The establishment of such
Farm Schools will add the dimension of **engagement with farm families**, to
extension.
iv) **Capacity building in post-harvest technology:**
This is an urgent task, particularly with the initiation of a National Horticulture Mission. **All existing KVKs should be equipped with facilities for training in post harvest technology as soon as possible.** Capacity building in post harvest technology, and imparting quality literacy (*Codex alimentarius* standards of food safety) are absolutely essential for realizing the goal of enhancing the productivity and quality of horticulture crops.

v) **Dryland Farming:**
Large scale demonstrations may be initiated with hybrid **Arhar** (*Cajanus Cajan*), to initiate a productivity revolution in pulses. Application of micronutrients, and introduction of new implements are other urgent tasks.

vi) **Horticulture:**
Organise **Small Holders’ Horticulture Estates**, to provide the power of scale to small producers at the production and post-harvest phases of the horticulture enterprises; increase investment on post-harvest technology and quality literacy; organize **horticulture seed villages** to produce and market good quality seeds and planting material and to generate new opportunities for skilled employment for rural women.

vii) **Cotton:**
Streamline Mission Management and organise Small Holders’ Cotton Estates. Replicate Maharashtra’s organic cotton experience, wherever feasible. Increase import duty on cotton by 30% as recommended in our first report.

viii) **Livestock and Livelihoods:**
The Union Minister for Agriculture and Food has rightly emphasized in his address to the NDC the importance of livestock in ensuring minimum income and nutrition security to small farm families. Breed, feed and health management hold the key to enhancing livestock productivity. Breed improvement in a slow process, except in poultry. Improved nutrition will help to increase milk-yield by at least 50%. Fodder and feed are the major constraints in improving productivity. Hence, a **Livestock Food Corporation of India** may be organized for the purpose of promoting the growth of Fodder and Feed Self-Help Groups (SHGs).
and Fodder and Feed Banks set-up all over the country by local SHGs with financial support through NABARD and financial institutions. The Livestock Food Corporation should not be organized on the lines of FCI, but should be a promotional, facilitating and mentoring organization. If innovative steps for increasing the production of good quality fodder and feed are not taken, farm animal productivity will go down further. To make a significant impact on poverty reduction, our animal husbandry programmes should be pro-poor and pro-women. Since good grazing lands hardly exist now, we have to rely on stall-fed livestock enterprises. The proposed Livestock Food Corporation can also promote the fortification of all cellulosic biomass like rice straw. Its major aim should be to ensure fodder and feed security in all parts of the country. At the same time, all Central and State government farms should be maintained for fodder and feed production under the umbrella of the Livestock Food Corporation of India. They should not be handed over to private parties for non-agricultural uses.

ix) Harnessing Gram Panchayats and Gram Sabhas for spreading sustainable agricultural practices and quality and trade literacy:
The Eleventh Schedule (Article 243G) of the Constitution 73rd Amendment Act 1992 lists “agriculture, including agricultural extension” as the first among 29 items entrusted to Panchayats for attention and action. There are nearly 240,000 elected Panchayats and local bodies in the country. There are also more than one million elected women members of the Panchayats. If Panchayats are empowered technically, financially and legally to assume these responsibilities, they could become catalysts of accelerated agricultural progress, particularly in the areas of sustainable natural resources management and productivity enhancement. Atleast one male and one female member of each Panchayat could be trained in integrated pest management, integrated nutrient supply and scientific water management, so that they could promote the group endeavour needed for success among farm families.

x) Restructuring the management of Technology Missions in order to enable them to respond to farmers’ needs in an integrated manner:
a) In our first report, we had recommended that there should be a convergence of appropriate Technology Missions around a Watershed or the command area of an irrigation project. This is essential to derive maximum benefit in terms of yield and income from the available water resources.

b) A Technology Mission is one, which is technology rich, and which is characterized by well defined outcome indicators and monitoring tools. It is also characterized by an end-to-end approach, covering all steps in the cultivation-consumption chain. The Mission Director should be an eminent professional who is likely to occupy the position for at least 5 years and who will be accountable for the success of the Mission. Unfortunately, the Farm Technology Missions are tending to become subsidy rich and technology poor. Accountability is also lacking, with the result that in several important crops like pulses and oilseeds, home production is stagnating and imports are increasing. This is one of the causes for the expanding farmers’ distress in dry farming areas. The smaller the farm, the greater is the need for productivity improvement, so that the farm family can have additional marketable surplus.

c) Enhancement of small farm productivity coupled with assured and remunerative marketing opportunities is the most effective means of reducing rural poverty. Fortunately, there is much scope for enhancing productivity even with the technologies currently on the shelf, provided market linkages can be tied up. This is where farmer-centric cooperative group and contract marketing can help. It should be emphasized that agricultural decline is not just the result of supply side factors related to input use and extension, but also due to a slow growth in demand. The real per capita food consumption decline is absolute in the case of cereals, pulses and edible oils. Since small and marginal farmers constitute a substantial proportion of India’s population, consumption will go up, if such farm families have access to more income.

xi) Credit supply and reform:

At the macro level, in 2004-05, the agriculture credit of Rs 1,15,000 crores made available exceeded the target of Rs. 1,10,000 crores, according to the Banking Division of the Union Ministry of Finance. It is not so much lack of credit availability but the
interest rate at which loans are given to resource poor farmers that is the major problem today. If marketing is also not pro-small farmer, the capacity to repay loans gets diminished. **Hence credit reform should include not only enhancement of the total amount available for farm loans, but also a reduction in interest rates and linkage with market.**

### 1.5.0 Immediate Steps to avoid the tragedy of farmers’ suicides

1.5.1 The following steps have been suggested by experts and farmers’ associations working in this area:

**i) Credit and insurance:**

a) Repeal the Public Demand Recovery Act, enacted by the British between 1904 and 1912, under which farmers could be jailed for defaulting the State for a paltry sum.

b) Create a corpus (on the line of calamity funds) for assisting farmers affected by crop losses.

c) Reduce the rate of interest for crop loans to 4% simple, with Government support, instead of compound rate of interest for arrears. Amendments to the Banking Act in the 1980s, has enabled banks to charge compound interest for bank arrears. This multiplies the farmers’ outstanding dues thereby driving them to despair, particularly under conditions where pro-small farmer marketing arrangements do not exist.

d) The more the poverty levels, the higher appears to be the rate of interest. In the Kalahandi belt of Orissa, known for endemic hunger and starvation, farmers receive loans from private money-lenders at a stupendous interest rate of 460 per cent. In neighbouring Madhya Pradesh, the rate of interest varies from 160 per cent to 250 per cent and in Jharkand, tribals in Palamau district pay back at a rate of 130 percent. These poverty stricken areas should receive top priority for credit access.

e) Interest on loans in areas hit by drought and floods and for crops under heavy pest infestation, needs to be waived.
f) Ensure transparency at the block level for proper credit disbursal by involving panchayats, farmers’ organizations, other civil society organisations and district administration. The credit disbursal system is ridden with corruption; it is reported that in Bihar, the block office often siphons off about 20% from every loan sanctioned – the situation may be somewhat similar in other states also and deserves urgent verification and correction.

g) Reduce crop insurance premium to increase cover. At the same time, crop insurance cover needs to be immediately expanded to cover the entire country and all crops.

h) Announce a moratorium on debt recovery including loans from non-institutional sources in distress hotspots, till reasonable profit margins are recorded; stagger debt recovery in easy installments. For this purpose, liquidity support will have to be provided for localized banks like RRBs and District Central Cooperative Banks.

i) At present credit is generally available only for improved technologies like hybrid crops, crossbred cows, etc. There is a need to de-link the availability of credit from technology. Credit should also be available if the farmer is adopting sustainable farming practices including the upkeep of traditional breeds of cattle. NABARD could develop a suitable project for low external input sustainable agriculture and aquaculture (LEISA).

ii) Irrigation and Cropping Pattern:

a) Regulate cultivation of water intensive cash crops in “dark and grey zones”. All new crop varieties being introduced in the country from any source should be assessed for their water requirement.

b) Agronomists should present their data not just on the basis of productivity per hectare but on the basis of net income per unit of water.

c) Intensify programmes for the rejuvenation of traditional water harvesting structures and creation of new ones and implement the recommendations contained in the first report of NCF.
d) Introduce measures to prevent further exploitation of groundwater in the dark zone, whether by public or private parties.

**iii) Inputs:**

a) Introduce appropriate legislation to regulate and deter the sale of spurious seeds and chemicals.

b) Marketing of inputs through retail shops may be assigned to registered agricultural graduates. Like the chemist shops, the agri-input shops could also be run exclusively by agriculture graduates. Women agricultural graduates could be encouraged and helped to start such Agri-input shops.

c) Promote community-based and managed seed production and marketing units at the village level and organize seed villages for this purpose.

d) Promote integrated pest management and integrated plant nutrient management systems.

**iv) Agriculture Marketing and Prices:**

a) Implement MSP for coarse cereals and pulses, which are the primary crops in rainfed drylands across the country. MSP as well as procurement need to be strengthened in the suicide hotspot areas of Andhra Pradesh, Karnataka, Kerala and Maharashtra.

b) Create a corpus for stabilizing price fluctuations.

c) Introduce quantitative restrictions on imports of farm commodities which constitute the backbone of the livelihood security system in dry farming areas.

1.5.2 The suicides of farmers are a symptom of a larger process, a reflection of a far wider rural distress. Thousands of households that have not seen suicides are also in the distress zone and hence should receive urgent attention.

1.5.3 Based on the above suggestions, it would be prudent to introduce a **Farmers’ Livelihood Security Compact**.

1.5.4 The Farmers’ Livelihood Security Compact could consist of the following integrated package of measures:

1.5.4.1 **Farmers’ Voices: Farm men and women** have plenty to say. Yet, information from their side hardly seems to be heard with any degree of seriousness by the authorities
who should be listening. If we do not listen to them, the suicides will not stop. There must be regular interaction between relevant authorities and small farmers as a first step. **State level Farmers’ Commission** could be set up for the purpose of ensuring dynamic government response to farmers’ problems.

1.5.4.2 **Census of Suicides**: It would be prudent to take note of field realities, which force farmers to end their lives. Reliable statistics will help to measure the impact of redressal measures.

1.5.4.3 **Urgent stepping-up of credit**: Inspite of Government pronouncements, credit is, becoming increasingly difficult to access. Indeed, official policies and agencies at all levels are making access to credit more difficult. According to one expert, the Cotton Federation in Vidharbha, which was set up to aid small farmers, *acts instead as a loan recovery arm of the banks*. So farmers who have had a bad year in 2004 may not go to the Federation with their produce in 2005 even if they have a good harvest. The Federation would cut their bank loan amounts from the meagre payouts. Which means the farmers would turn to private traders and will not be able to access the minimum support price. Many of the Vidharbha suicides were of farmers who had lost hope in the Federation and turned to private traders.

1.5.4.4 If we cannot urgently address the problem of credit, we can forget about even slowing down the suicides, let alone stopping them. A **paradigm shift from microfinance to Livelihood Finance is called for**. So serious is the credit crisis that in a few instances small moneylenders have also taken their lives. This is because their clients have all unavoidably defaulted. There is also an incredible amount of fiddling with what credit for agriculture means. So-called Grameen banks are giving loans not for agricultural activities but for constructing buildings of private hospitals, private colleges, and even company showrooms. This is within their largely rural districts, and can be passed off as rural credit. There is need to check the break-up of the loans given by Grameen banks.

1.5.4.5 **Debt survey**: There is an urgent need for a proper All-India Debt Survey conducted on very different terms. The survey should take into account newer forms of credit and indebtedness and newer forms of bondage.
1.5.4.6 **Debt waiver:** For the smallest and the weakest, a debt waiver would bring some immediate relief. The amount that is to be the cut-off point could be worked out in consultation with Panchayats and farmers’ representatives in the distress hotspot areas.

1.5.4.7 **Insurance revival:** Owing to no fault of their own, lakhs of farmers have seen their insurance policies lapse after the initial two payments. There are provisions in the insurance laws that allow LIC to revive the lapsed policies. Indeed, it would be in the interest of LIC to do so. If done, in Andhra alone, this would place Rs. 1,000 crore back in the farmers’ accounts and give many a sense of confidence.

1.5.4.8 **Parivar Bima Policy:** The integrated family insurance policy recommended by NCF in its first report deserves to be examined and introduced, to begin with, in dry farming areas. The example of Assam in this respect is worthy of being followed by other states.

1.5.4.9 **Urgent need for employment:** The slow and halting march of the employment guarantee scheme and food-for-work programmes is a matter of utmost concern. Not only is distress mounting in rural households, migrations are increasing. In Kerala, famous for out-migration, Wayanad was the one district that saw little of it and, in fact, had considerable in-migration. All that has changed with the agrarian crisis. From districts like Mahbubnagar in Andhra Pradesh, migrants go in lakhs seeking work in Mumbai and its surrounding regions. Many go to astonishingly far-off places in other parts of the country, driven by hunger and an absence of work. Indeed, the employment guarantee in its present version will not even begin to meet this problem. A radical approach to creating far more days of work is crucial at this point. The proposal to bring an additional 10 million ha under assured irrigation and the other components of the Bharat Nirman programme would help to enlarge employment opportunities in villages.

1.5.4.10 **Policies for Irrigation Water:** Water conservation, equity and fairness and public good will have to be the basis of water policies. Privatization should not work against the interests of small and marginal farmers. In the small town of Hindupur, in AP, residents are spending an estimated Rs. 8 crores a year on drinking water. Farmers meanwhile, pay up to Rs. 12,000 for a single ‘wetting’ of their water-starved fields. Irrigation policies need to be viewed in a holistic manner and made pro-poor.
1.5.4.11 **Revising import policies:** In the context of the Kerala suicides, there is an urgent need for a revision of existing rules. Inferior quality pepper is entering the state in thousands of tonnes and, after being mixed with Malabar pepper, is then being exported to overseas markets as Indian pepper. This is destroying the market for genuine Malabar pepper - the best (premium quality) in the world. And many suicides are indeed linked to the crash in the prices of pepper and coffee. The government order of December 2004 stopped such imports from most countries except Sri Lanka. This loophole is being systematically exploited ever since. Low-grade pepper from places like Vietnam and Indonesia now first goes to Sri Lanka (*where it enters with no duties*). All this then enters India as “Sri Lankan pepper” when it is in fact nothing of the sort. The measures of the Kerala government to meet this crisis involve policing farms in Wayanad, while it is the import policy that needs review.

1.5.4.12 **Addressing the problem of cotton:** Some swift action on import duties is also a must in the case of Vidharbha’s poor cotton farmers. Nearly 30 lakh people are dependent on that crop for their livelihoods. With great difficulty, they managed to have the import duty on cotton raised from five per cent to ten per cent. In contrast, the duty in the case of import of sugar is 60%. The cotton growers head the list of farmers who have committed suicide in Maharashtra and hence deserve to be treated on the lines of the sugarcane farmer. The estimated purchase of cotton in Maharashtra during this year is 202 lakh quintals at a cost of Rs. 4600 crores. However, the amount paid was only Rs 750 crores. Since cotton farmers did not get their full payment, they were in distress. Monopoly intervention in cotton purchase by State Governments needs careful review. Also, in our first report we had recommended increasing import duty on cotton to 30%. This needs to be implemented immediately.

1.5.4.13 **Ending extortion in tenancy rates:** In Andhra, quick moves need to be made to end extortionist rates of tenancy and lease. Many small farmers, in coastal AP for instance, are crushed by having to part with over 80 per cent of their produce as rent. **There is an urgent need to implement land reform measures. Some of these already exist and need to be enforced.**
1.5.4.14 **Investment in agriculture:** The misery of farmers cannot be halted if urgent steps are not taken to increase investment in agriculture to a far greater level than it is now. The agrarian crisis is a component of a far wider and deeper rural distress. **Even if agriculture’s share of GDP has dipped, its centrality to life is such that every section and sector do badly when agriculture does badly.** Suicides of farmers are followed by hunger deaths, for instance, amongst carpenters and weavers as in the case of Andhra Pradesh, who have lost both their market (with the falling purchasing power of their clients) and also their meagre subsidies.

1.5.4.15 **Access to affordable inputs is crucial:** No less important than listening to the farmers is to undo the extraordinary damage that harmful policies have inflicted on them.

   i) Input prices have simply shot up and are still escalating. It is possible today that a farmer in Telangana owning eight acres of paddy land may still be below the official poverty line. The government must urgently intervene to ensure that seed and other inputs reach farmers at affordable costs and at the right time and place. Resource poor farm families should not be left to the mercy of input dealers who have emerged as the new moneylenders of the countryside.

   ii) Quality control is becoming increasingly important. For example, in the district of Yavatmal in Maharashtra, 1,200 shops have sprung up selling seed and other inputs. There is one quality control inspector to oversee the lot. This is a region where re-sowing has frequently occurred, not merely due to poor rainfall but also due to sub-standard inputs like poor quality seed. The maximum punishment for selling fake seed (except where new laws have been passed) is a meagre Rs. 500.

   iii) **Appropriate regulation an urgent must:** Control has also to be exercised over false and exaggerated claims for inputs. It is frightening that desperate farmers are going in for unproven and poorly tested inputs on a large scale in sheer desperation. This being done often will increase credit obtained from moneylenders. Quality control is especially urgent in the case of bio-fertilizers and bio-pesticides.

   iv) The setting of standards means the re-introduction of firm regulation where required. Companies have drastically lowered the minimum germination rate they assure farmers. In the case of seed, this has fallen to as low as 60 per cent. This
means a village buying 1000 bags of seed pays for that number, but gets only 600 in effect. Such unscrupulous groups, companies and individuals pushing such practices must be brought to book and accountability must be ensured.

1.5.4.16 Overhauling farmers’ markets: Swift action is required to overhaul the ryuthu bazars or farmers’ markets. Most of these are presently controlled not by farmers but by traders, from whose control they must be released. Even the “farmers’ markets” are now heavily loaded against the small producers. Cartels and trader networks manipulate these and rig prices systematically. Amendments to APMA, as suggested by the Union Agriculture Ministry, need to be carried out by State Governments as soon as possible. Several State Governments have already taken action to reform the agricultural marketing system. There is also need for introducing focused Market Intervention Scheme.

1.5.4.17 Extension work: Several states have been systematically withdrawing from extension work. Few things could be more problematic, at a time when the farmer is desperately and urgently in need of sound advice and expertise on a range of issues.

i) The vital role of the Agriculture Extension Officer must be recognised and the system revived and strengthened. At the same time, Farm Schools should be established at the grassroot level.

ii) Quite a few farmers took their lives after crop failures, which in some cases could have been avoided by timely advice and technical assistance. There is also a tendency among some resource poor farmers to take to high cost technology without the capacity to incur losses due to factors beyond their control. In this context, it is also important to re-state the role of Agricultural universities. In some cases, major input dealers sit on the governing bodies of such universities and this often leads to major conflict of interests. Linkages between agricultural universities and farm communities must be completely restructured and strengthened.

iii) Agricultural and Animal Sciences Universities could form Hope Generation Teams (like NSS) of young male and female students who could stay in the distress villages during vacations and extend both technical and psychological support. The universities must be accountable to the farming community and not to private interests. The needs and demands of the community must be the first priority of such
bodies. The universities must also undertake a serious study of existing and emerging cropping patterns in their regions. The peripatetic hope generation teams could be a timely response to the crisis situation.

1.5.5 Basic services: Ultimately, steps to prevent farmers’ suicides cannot be divorced from steps to end the larger rural distress. That in turn cannot be de-linked from our overall policy framework. The distress sweeping rural India flows from the gradual collapse of public services. For instance, almost all the suicide and otherwise crisis-hit households record high health expenditures. Indeed, that is emerging as the second-fastest growing component of rural family debt. Yet the privatisation of basic services will only worsen this situation. There are documented instances of farmers mortgaging all their land in order to raise private loans to pay off health bills. There is urgent need for both affordable health insurance, as recommended in the first report of NCF and the revitalization of primary health care centres.

1.5.6 Likewise, the commercialisation of education is taking its toll on students from poor farm families in even the most educated state of them all - Kerala, particularly in crisis-hit Wayanad district. In rural Andhra, there are school students who have simply stopped going because their parents cannot afford the bus fare. The privatisation of utilities or the massive hikes in rates has also been a factor in farmers’ distress. In Andhra, the state shut down the irrigation development corporation in 1997. This was, predictably followed by a huge rush for private borewells. For an overwhelming number of those in distress in Andhra, their crisis was linked with water and borewells. There were years when spending on borewells was the major cause of debt.

1.5.7 Knowledge Empowerment: In addition to the above steps, there is need for establishing Village Knowledge Centres (VKCs) in the farmers’ distress hotspots. These VKCs could be linked to a Block level Village Resource Centre (VRC) with the help of the Indian Space Research Organisation (ISRO). This will enable tele-conferencing and thereby facilitate immediate attention to distress calls. The VRC-VKC grid could provide dynamic and demand driven information on all aspects of agricultural and non-farm livelihoods. These centres of hope in areas where rural families had lost hope should be operated to the extent feasible, by the wives or children of the farmers who had unfortunately taken their lives. This will help to impart realism and a right sense of
priorities in the creation of content. Training and capacity building in the operation of such centers need to be done in local languages. ISRO has agreed to help in organizing such Knowledge Centres in the distress hotspot areas of Mahbubnagar, Wayanad, Vidharba and Karnataka in association with M S Swaminathan Research Foundation, Chennai.

1.6.0 Enlarging the export of farm commodities:

1.6.1 Safeguarding our position in Basmati rice exports:

In its report on agricultural biotechnology, the Swaminathan Committee had recommended that no genetically modified rice should be released in the name of basmati, since many countries including Europe have not approved the sale of genetically modified foodgrains. The Agricultural and Processed Food Products Export Development Authority (APEDA) and the All India Rice Exporters’ Association have brought to our attention another serious threat to our basmati rice exports.

While questioning the Rice Tec Patent in the United States, the characteristics of Indian Basmati were defined on the basis of the following three criteria.

a) A set of physical parameters such as length, breadth, elongation ratio and slenderness ratio.

b) Linkage to the original land races that trace back their history to poems of Heer-Ranjha and 18th century documentation.

c) Grown in geographically well-defined areas

1.6.2 Based on the above, the Ministry of Commerce notified Basmati standards under the E1A on 23 January 2001. Inspite of such clarification, several high yielding semi-dwarf stature aromatic rices are being released by research institutions under the name Basmati. Such a dilution of the pristine properties of traditional Indian Basmati, is now seriously threatening our export earnings from Basmati rices. Also, the “dwarf basmati” grains are being used for adulteration with traditional basmati varieties.

1.6.3 Research on new aromatic long grains should be encouraged but such varieties should be marketed under appropriate names and should not be called basmati. Basmati is not the only premium rice. Hence, new long grain, aromatic rices can stand on their own in the international markets without be termed basmati. It would
be in the interests of both farmers and the country, that we maintain the Indian basmati varieties, which are valued very highly in the international market, in their pristine purity. Otherwise, Pakistan basmati will eclipse the numerous strains being marketed from India, carrying the name basmati in the international market.

1.6.4 Therefore, the Ministry of Agriculture and ICAR should evolve a policy for ensuring that the appellate basmati is used only for traditional fine grain aromatic rices of great antiquity and of a specific geographic origin. The new high yielding fine grain aromatic rices can be given other appropriate names, since they have a good market potential without being called basmati. They can stand on their own merit, without diluting the historic halo, which surrounds the traditional Indian basmati rice.

1.6.5 We would urge that the following points may be kept in view in the area of nomenclature:

   i) The dilution of Basmati definition is not in the interests of either Basmati or the new varieties.
   ii) All long grain aromatic strains should not be called basmati.

1.6.6 In our first report, we had emphasized the urgent need for strengthening our infrastructure for sanitary and phytosanitary measures and for launching a trade and quality literacy movement among farm families. APEDA may be enabled to help Agricultural Universities organize a 1 Credit Course (12 lectures) for all Agricultural and Home Science College students on external trade opportunities and on methods of sustaining and expanding our agricultural exports.

1.6.7 There is need to explain the features of Codex alimentarius standards of food safety in villages. This can be done through the proposed grid of Village Knowledge Centres. Now that the Doha round of negotiations in agricultural trade are nearing completion, we should lose no further time in helping our farm families to become quality conscious, with reference to both home and external markets. Our agricultural competitiveness in the external market can be improved only if we help farm families to increase both productivity and quality of crops in demand in the global market.

1.7.0 Beyond Tsunami: Agronomic Rehabilitation of Tsunami affected coastal agriculture:

1.7.1 In the first report of NCF, detailed suggestions had been offered for the psychological, ecological and livelihood rehabilitation of tsunami affected coastal areas
in Tamil Nadu, Kerala, Pondicherry and the Andaman and Nicobar Islands. The main instrument for ecological rehabilitation is the establishment of bioshields, while the biovillage model of sustainable on-farm and off-farm livelihoods is the most effective pathway of ensuring work and income security. In several places, the seawater had entered prime agricultural land adjoining the coast, rendering both soil and water saline. About 6,000 ha of farmland are estimated to be affected in Tamil Nadu and Pondicherry. Ad hoc recommendations were being given to the affected farmers by both NGOs and government departments. **In particular, the indiscriminate application of gypsum was being recommended.**

1.7.2 NCF therefore organized a Travelling Workshop by a Team of Scientists drawn from the Central Soil Salinity Research Institute, Karnal, the Central Salt and Marine Chemicals Research Institute, Bhavnagar, the National Institute of Oceanography, Goa, the National Bureau of Soil Survey and Land Use Planning of ICAR, IARI, ICRISAT, the Tamil Nadu Agricultural University and MSSRF, from 16-18 July, 2005. Based on their advice, the following recommendations are made for the use of extension and research workers engaged in helping farmers in tsunami-affected areas to restore the health and productivity of their soils. **It is recommended that these recommendations based on the best possible technical expertise available in the country may be communicated to the concerned State Governments and the Andaman and Nicobar Islands administration by Secretary, Agriculture.**

1.7.3 **Recommendations of the Travelling Workshop**

1.7.3.1 Tsunami waves caused extensive damage to the basic agricultural resources like soil and water as well as to standing crops like paddy, groundnut, etc in some of the regions of Tamil Nadu and Pondicherry. Across the affected areas, the intensity as well as type of the damage vary. Since the devastating incident took place, the Department of Agriculture, Tamil Nadu along with concerned research institutes and NGOs have been involved in rehabilitating the affected farmland.

1.7.3.2 To understand the multi-dimensional nature of the problem and to develop science-based soil health rehabilitation packages. The participants of the workshop visited around nine villages (spot measurements for pH and EC were conducted and
discussions with farmers were held) in Nagapattinam and Cuddalore districts on 16\textsuperscript{th} and 17\textsuperscript{th} July 2005. On 18\textsuperscript{th} the team met at Chennai, discussed their field observations and arrived at the following recommendations:

1.7.3.3 Soil Health Restoration

Tsunami waves caused three kinds of damages to soil. These are:

a) Deposition of slushy grayish brown clay,
b) Deposition of sand, and
c) Sea water intrusion, which receded (within 3 hrs to one week from the field) leaving salts in the field

a) Deposition of slushy grayish brown clay deposit

This kind of damage was noticed exclusively in the southern parts of Nagapattinam district where the clay deposit thickness varied from 5 cm to 30 cms height. After drying it was 2mm to 50mm thick. The chemical analysis of the deposited material showed that it is rich in organic matter (0.6 – 1.2\%), having good water holding capacity and cation exchange capacity with an Exchangeable Sodium Percentage of 55\%. During the field visit (16\textsuperscript{th} July 2005), the pH and Electrical Conductivity (EC) of the sediments, which were scrapped and heaped in the field were found to be nearly 8.6 and 12.7 ds m\textsuperscript{-1} respectively.

Problems caused by clay surface deposits: Crust formation leading to physical barrier for aeration and germination; High amount of salts leading to the development of salinity; Danger of toxic material (heavy metals)

Management of clay deposits: The deposit can be mixed with soil by ploughing and it will improve soil texture, especially of the surface soil, water holding capacity and soil fertility. The incorporation of deposited material will not act as physical barrier since it cracks on drying and after mixing. The higher amount of salts will get leached down after the rainy season and thus it will not be a permanent source of salts, which could affect adversely the root growth. The deposit was scrapped and kept by some farmers in the field itself as heaps. It should be spread and incorporated into the soil to avoid the development of acute localized salinity.
b) **Management of soils with sand deposition**

This kind of damage was noticed in the mid and northern villages of Nagapattinam districts and southern regions of Cuddalore district. The thickness of the deposit varied from 2 – 5 cms. The deposit was scrapped and heaped in the field itself by some farmers. The analysis on 16\(^{th}\) and 17\(^{th}\) July 2005 showed a pH of nearly 6.5 and an EC of 8.3 ds M\(^{-1}\).

**Management of Sandy soils:** The sand deposit need not be scrapped, but may be ploughed back in the field itself. Wherever the material has been collected and left in the field as small heaps, it should be spread again in the field and mixed with the soil. Leaving the deposits as heaps in the field will aggravate local salinity.

c) **Seawater inundation**

This kind of damage was noticed in a few areas of Nagapattinam and Cuddalore districts. The seawater entered the field directly as well as through backwater canals. The water receded within a few hours (quickly) in some areas, and after five to seven days (slowly) in some other farms. Soil analysis shows that the soils have become salinised and not sodic and the soluble salts are dominated by Cl and SO\(_4\) and not by CO\(_3\) and bicarbonates. Hence, during leaching the pH will not go up, ESP and EC will decrease simultaneously during the reclamation process. Different soil depth analyses indicate that the top 0-2 cm depth soil has an EC of 25-120 ds m\(^{-1}\) with a pH of 7.2 - 8.2.Hence leaching with sufficient amount of canal water or rainfall will help to overcome the problem. Normally, rainfall should be heavy in this region during the Northeast Monsoon season (October-December).

**Use of gypsum:** A blanket application of gypsum for reclamation in the entire affected areas should be avoided. Gypsum application should be location specific i.e. where the pH is >8.5, ESP>15 and in cases where during reclamation the pH increases. It should be followed purely on the basis of soil test results.

The gypsum already supplied to the farmers at the rate of 500 kg per hectare could be used as a fertilizer to meet the calcium and sulphur nutrition needs of oil seed
crops like gingelly (seasame) and groundnut. In such cases the recommended dose would be around 100 to 200 kg/ha.

**Use of Organic Manure:** The soils are sandy in texture, and have low amounts of organic carbon. Farmers should be encouraged to go in for green manuring in addition to the judicious application of FYM, compost and biofertilizers.

**Restoration of water ponds inundated with seawater and deposits:** Most of the small water ponds located in the fields which are the source of irrigation for the second and third crop, were severely affected and at present the water is saline.

1.7.3.4 Agricultural Departments and farmers should be advised to take the following measures:

i) Physical removal of contaminated water through tankers and connected pipelines thus paving way to receive monsoon rains

ii) Surface leaching through rainfall and canal water

iii) Promoting rain water harvesting in household and farm ponds

iv) Desilting and interlinking drainage channels to facilitate the easy flow of water.

1.7.3.5 Desirable Cropping Systems:

The following crops and varieties are suggested for the forthcoming season in Tamil Nadu and Pondicherry:

a) Salt-tolerant crops/varieties have to be grown in the first year and the first crop should be preferably rice

b) Rice – TRY 1, TRY (R) 2, CO 47, ADT 43 and ADT 36

c) Ragi – TRY 1, Sunflower – CO4, Groundnut – VRI 2

d) Green gram (K 851, Pusa bold)

e) Brinjal (PLR 1, AU 1), Cluster bean (Pusa Now bahar)

f) Jack fruit (Palur 1), Pomegranate (Ganesh), Sapota (PKM 1)

g) Cashew (VRI 2 & 3), Amla (BSR 1) and Tamarind (PKM 1)

1.7.3.6 Specific agronomic practices for Rice

a) Aged seedlings (one week more than normal age) may be planted

b) Higher number (4-6 Nos.) of seedlings per hill may be planted

c) 25% extra N as basal dose may be added
d) Higher dose (40 kg/ha) of zinc sulphate has to be applied

e) At panicle initiation and 15 days after, foliar spraying of DAP 2% along with 1% urea and 1% potash may be done for increasing the yield

f) Soil testing based P application or apply 15 kg P/ha as maintainer dose

g) Sowing sprouted seeds (3 days) under delayed canal water availability or excess rainfall

1.7.3.7 **Application of FYM and Micro nutrients:** 12.5 t/ha may be applied for all the crops

1.7.3.8 **Promote integrated farming systems** involving crop-animal combination with suitable animal breeds and allied enterprises

1.7.3.9 **Crop diversification:** Promotion of horticulture and tree crops and value addition to the produce will help to increase income and employment. It would be in the interest of farmers to accord high priority to horticulture.

1.7.3.10 **Multiple Livelihoods:** There is a need to promote additional on-farm and non-farm enterprises like the preparation of coconut based value added products, apiculture, dairying, small growers poultry estates, cashew processing, production of bio-fertilizers and bio-pesticides. This would promote multiple employment opportunities not only to the majority of small and marginal farmers but also to the landless labourers who form a sizable part of the local population and who have lost their livelihood opportunities.

1.7.3.11 **Demonstrations of Agronomic Rehabilitation Practices:** It is suggested that a special demonstration cum field verification programme may be organised in tsunami affected agricultural areas based on an integrated crop-livestock farming system. The demonstrations may cover about 200 ha each and address the following major problems:

   i) Fields affected by clay deposits

   ii) Fields affected by sand deposits

   iii) Areas affected by seawater inundation

   There could be a combination of the above 3 forms of soil health hazards in some areas.

1.7.3.12 **The “Beyond Tsunami” Agricultural Rehabilitation Demonstration programme may include the following components:**

   i) **Soil health restoration**
ii) Water management and sea water replacement

iii) Crop and varietal choice

iv) Introduction of livestock farming for supplementary nutrition and income

v) Producer-oriented marketing

vi) Training and capacity building

vii) Monitoring at benchmark sites of the impact of the rehabilitation measures

1.7.3.13 The Tamil Nadu Agricultural University and the State Department of Agriculture could initiate these demonstration cum training programmes with technical help from CSSRI, Karnal, CSMCRI, Bhavnagar, NBSSLUP, Bangalore and ICRISAT, Hyderabad. **Funds for the Demonstration cum Training programme may be provided from the Tsunami Relief Allocation at the rate of Rs. 20 Lakhs per demonstration, each covering an area of 200 ha. In all about 15 such demonstrations may be organized in the affected states and in Andaman and Nicobar Islands at a cost of Rs. 3.00 crores.** This will have to be done immediately, if the problems of the tsunami affected farmers are to be solved and their livelihoods revived.

1.8.0 Indo-US Collaboration in Agronomic Rehabilitation Strategy:

1.8.1 Earlier this year in the USA, a group of scientists, professional, and technical experts came together to address the contaminated areas that had little hope of recovery. This group of professionals became the **GreenLine Group.** The group includes experts in sodium remediation, composting, organic farming, water treatment and other measures to restore the muddy rice fields and river delta areas in India that have very high levels of contamination from sea water.

1.8.2 **GreenLine Group** has offered to work closely with scientists in India and seeks a site in Tamil Nadu where they can help to start the first phase programme on 100 hectare of farm land. This first phase will be used to adjust the practices and procedures to the region and establish a teaching center which will be used for education and training to scale up the programme to other areas and regions.

1.8.3 This programme will utilize many proven technologies used throughout the United States. Plans are in place to restore the damaged lands and soil, but also to improve the soil quality, water quality, and increase farm and aquaculture production in
these areas. Additionally, several key universities, including Texas A&M, Pennsylvania State, and Texas Tech, will contribute scientists and graduate students to this first phase two year programme. This can become an important programme to promote sharing of knowledge and technology.

1.8.4 The impact of this programme on the farmers of this region can be realized in as little as six months, by restoring farming activity. The timing of this project is critical to launch at the beginning of the October monsoon season. The US Team will meet its own expenses. We suggest that Rs.1 crore may be allotted for this collaborative programme from the Prime Minister’s Relief Fund, which will be implemented by MSSRF, ICRISAT and the GreenLine Group.

1.9.0 Mission 2007 – Every Village a Knowledge Centre

1.9.1 In its first report, NCF stressed the need for knowledge connectivity in rural India, since for enhancing our agricultural efficiency and competitiveness, farm families need urgently the right information at the right place and at the right time. We envisaged that knowledge connectivity should be a key component of Bharat Nirman designed to provide a New Deal for Rural India. The NCF proposal received support in the union budget for 2005-06.

1.9.2 Shri P Chidambaram, Union Finance Minister, made the following announcement concerning Mission 2007 in his budget speech on 28 February 2005 “The National Commission on Farmers has recommended the establishment of Rural Knowledge Centres all over the country using modern information and communication technology (ICT). Mission 2007 is a national initiative launched by an alliance comprising nearly 80 organisations including civil society organizations. Their goal is to set up a Knowledge Centre in every village by the 60th anniversary of Independence Day. Government supports the goal, and I am glad to announce that Government has decided to join the alliance and route its support through NABARD. I propose to allow NABARD to provide Rs. 100 crore out of RIDF (i.e. Rural Infrastructure Development Fund).”

1.9.3 In order to impart the needed momentum to the rural knowledge revolution, NCF organized in collaboration with NABARD a discussion in Mumbai in April 2005 to prepare a road map for organizing ICT-SHGs (Self Help Groups), to begin with in 10
states, where the infrastructure for the rural ICT revolution exists. NABARD will provide Rs. 1 lakh each to 10,000 ICT-SHGs during 2005-06.

1.9.4 NCF also helped to organize the second convention of the National Alliance for Mission 2007: Every Village a Knowledge Centre at New Delhi on 11-12 July 2005. The convention was addressed by the President of India, Union Ministers for Finance and Panchayat Raj and the Chief Ministers of Rajasthan and Delhi, in addition to leading experts.

1.9.5 Based on the discussions held at the National Convention, NCF recommends for the consideration of the Government of India the following 5 action points.

**Action Point 1:** The Government of India should include in the *Bharat Nirman programme* the establishment of Village Knowledge Centres (VKCs) in each of the about 237,000 Panchayats in the country. VKCs also need to be established in the local bodies in the North East region. Apart from providing generic and dynamic information in areas relevant to rural livelihoods and agricultural marketing the VKCs can help to provide meaning and content to the *Right to Information Act 2005*.

**Action Point 2:** *Convergence and Synergy among public and private sector initiatives:* There is need for convergence and synergy among the numerous initiatives of Central and State Governments in the area of ICT for governance and development. The following are some of the major initiatives.

i) National e-governance plan (NeGP) announced in October 2004 and the technical and financial support proposed to be extended to the State Wide Area Network (SWAN). Additional Central assistance is proposed to be extended to all the states for initiating NeGP.

ii) A well articulated Broadband Policy announced in December 2004, followed by a notification on 28 January 2005 on de-licensing of the use of wireless equipment in band 2.4 GHz to 2.4835 GHz between 1 and 4 watt power.

iii) Notification on de-licensing of indoor use of low powered wireless equipment including Radio Local Area Networks in the frequency band 5.150 to 5.875 GHz with the maximum effective isotropic radiated power, using the built-in or indoor antenna.
iv) Commitment of the Government of India to set up 100,000 VKCs by 2007 through the Ministry of Communication and Information Technology.

v) Announcement of financial support for content development to the Northeastern states for the creation and operation of 487 Community Information Centres (CICs)

vi) Decision of the Union Planning Commission to re-establish the DISNIC – PLAN project, with institutional linkages to grassroot organizations and covering all the districts indentified for Employment Guarantee through NIC.

vii) Commitment of the Ministry for Panchayati Raj for providing facilities to house VKCs

viii) Enactment of the Right to Information Act 2005

ix) Setting up of a National Knowledge Commission under the chairmanship of Dr Sam Pitroda

x) Numerous initiatives in the private NGO and public sectors such as e-chaupal of ITC, VKCs and Village Resource Centres of MSSRF and ISRO, and Unlimited Potential Capacity building programme of Microsoft.

The National Alliance for Mission 2007 could help in promoting interaction and synergy among all these important initiatives in the public and private sectors.

**Action Point 3: Connectivity and Content: National Digital Gateways:** A Connectivity and Content Consortia involving all relevant government, academic and private sector institutions need to be set up in every district of the country. They can be organized under atleast 4 National Digital Gateways relating to fields such as agriculture and agribusiness, education, health and livelihoods. These national gateways should focus and respond to the needs of the rural families, by collecting, processing, packaging and disseminating demand driven information in **multi-lingual and multi-media formats.** This will help to overcome language and literacy barriers.

Scientists from ICRISAT, IIT Kanpur and MSSRF have proposed that standard thesaurus such as AGROVOC of the FAO should be considered the basis for design of agricultural information portals in India in multiple Indian languages. The AGROVOC also permits addition of new terms that are specific to local cultural practices. Using semantic web technology, context specific searches can be carried out. A standards-based
contents design process can then emerge. Conversion of AGROVOC into a number of Indian languages will make the proposed national gateway for online agricultural information in India a reality. Other agricultural research institutions should get involved in the exercise to hasten the process of conversion into different languages.

1.10.7 The National e-governance Plan (NeGP) envisages the setting up of over 100,000 Community Service Centres. This will help to ensure that all the Central and State e-governance services are available on the Internet and through VKCs.

**Action Point 4: Capacity Building:** The rural families should have a sense of ownership of VKCs. The Gram Sabhas could provide guidance on priorities in information needs. Ultimately, at least 1 woman and 1 man will have to be trained in each village as Master Trainers. The Jamsetji Tata National Virtual Academy for Rural Prosperity could be developed as the umbrella organization for capacity building. The rural women and men elected as Fellows of NVA could help to manage VKCs and in providing the needed information at the right time. They will also train other rural women and men in computer techniques and in adding value to information so as to convert generic into location-specific information.

**A Consortium of Capacity Building Institutions** will have to be organized for each language of communication. We recommend that the Ministries of Rural Development and Panchayati Raj provide Rs. 50 crores each for such training and capacity building activities during 2005-06. Members of the Capacity Building Consortia could also undertake mentoring services until the time the VKCs become self-reliant. **The Union Ministry of Agriculture may also provide Rs. 50 crores annually during the next 3 years for content creation and capacity building in the areas of crop and animal husbandry, fisheries, forestry, agro-processing and marketing and for imparting quality trade and genetic literacy.** The various Farm Technology Missions could work with VKCs in spreading information relevant to the improvement of productivity and profitability.

**Action Point 5: Organisation and Management:** This is a crucial component of Mission 2007. The greatest challenge will be in the area of organization and management. Organisation of VKCs can be undertaken by multiple agencies such as the following:
i) **Gram Panchayat Centred VKCs** under the Bharat Nirman programme, with guidance and oversight from Gram Sabhas.

ii) Community Centred and managed VKCs through ICT-SHG with support through NABARD.

iii) Commercial ICT-Kiosk models promoted by business and industry, NGOs and academic institutions.

1.9.6 All methods of organization should be based on the principles of gender sensitivity, social inclusion and antyodaya, so that the rural digital divide does not become one more factor in enlarging the rich-poor and gender divides.

1.9.7 The Village Knowledge Centre will be an important step in Government’s plan to reach out to 200 million subscribers with connectivity and providing over 4,000 community radio stations. We also recommend that a single window, time-bound licensing policy be implemented for providing one ham radio per Panchayat in all the 237,000 local bodies in the country.

1.9.8 The frequencies that are foreseen internationally for new technologies such as Wi Max should be vacated at an early date, so that there could be massive savings in communication costs. Also, we recommend that Government should remove the service tax (10.2%) currently levied on Internet Bandwidth in villages. As a single step, this will help to remove an important barrier in extending ICT services to rural areas.

1.9.9 **Synergising the Common Service Centres (CSC) of Department of Information Technology (DIT) with Mission 2007:** The recently announced DIT scheme for setting up 100,000 CSCs in rural areas emphasises entrepreneurship and revenue generation as its prime objectives. As per the guidelines, the DIT scheme appears to preclude a number of professional and non-governmental organizations and community-based SHGs who may not have so far implemented Knowledge Centres but would do so given an opportunity. The CSCs to succeed, should be inclusive, pro-poor and pro-women and should provide the necessary forward and backward linkages to the farmers, especially to the poor farmers, with value-added, locale-specific knowledge. It is important to ensure that farming communities run the CSCs with support from their Panchayats. The NCF recommends that the DIT scheme for Common Service Centres is brought under the umbrella of Mission 2007 and implemented as a part of Bharat Nirman. A monitoring
agency with strong civil society participation may be set up to ensure that the CSC scheme attains the national objectives.

1.9.10 Finance and Policy Support: NCF urges Government to make knowledge connectivity the backbone of other forms of rural connectivity. **We have an uncommon opportunity to take the digital revolution to rural India. What we need is a coherent and interactive package of public policies, and not too many fragmented and isolated initiatives and policies.** Since farm families constitute the vast majority of the rural population, we urge the Ministry of Agriculture to facilitate a Rural and Agricultural Knowledge Revolution through a coordinated action plan.

1.9.11 The Telecom Regulatory Authority of India (TRAI) has proposed the concept of **Rural Service Provider (RSP).** The BSNL/MTNL’s fibre optic network covers over 600,000 kms and nearly 97% of the optic fibre remains unlit dark fibre. **This is a huge unused national resource of inestimable value for Bharat Nirman.**

1.9.12 The RSP license should allow for the provision of telephone, internet and radio services exclusively for the rural areas with no license fee levied until 2010. The RSPs should be allowed to use any technology that may be appropriate to provide the rural families with the needed services. They may be allowed to connect with the **Taluka** headquarters through any national network on the revenue sharing bands. Long distance connectivity may also be provided free of cost to RSPs until 2010. As recommended by TRAI, the costs could be met from the USO fund. Wherever feasible, unused optic fibre bandwidth may be procured from this purpose, supplemented by bandwidth from VSAT and DTH service providers to cater to the needs of data broadcasting and reaching the unreached.

1.9.13 The process of obtaining the RSP license should be simple and transparent. We recommend that the Ministries of Agriculture, Rural Development, Panchayati Raj, Communication and Information Technology and Home may jointly develop a simple set of procedures.

1.9.14 A total of about Rs.3000 crores of public investment may be needed during the next 3 years for making the ‘Every Village a Knowledge Centre’ concept a reality. We suggest that investment in the VKC programme should come from a variety of
government sources including the USO fund and the vast resources being set apart for Bharat Nirman. **Until 2010, the aim should be the knowledge and skill empowerment of rural women and men with public funds.** We are confident that the rural knowledge managers (ICT- SHGs) and the Fellows of the Jamsetji Tata National Virtual Academy will develop during the next 5 years the capacity to earn adequate funds, through facilitating the outsourcing of appropriate government and private sector activities from the urban to rural areas.

1.10. 0 Producer Oriented Assured and Remunerative Marketing: Role of Commodity Futures Markets

1.10.1 **Opportunities for assured and remunerative marketing hold the key to sustaining farmers’ interest in increasing productivity.** As already emphasized, we should increase rural non-farm income, so that the purchasing power of the rural poor goes up. Only then will home consumption show improvement. In early 2003, the Government of India liberalized procedures for the establishment of commodity future markets. As a result, this market is expanding at a fast pace. The trade turnover in the commodity exchanges touched Rs. 5,70,000 crores during 2004-05. The time has come to ensure the healthy and regulated growth of this market and make small farmers benefit from the development of this market. If spot and futures prices of farm commodities are available to farmers as well as to the agro-and food processing industries through VKCs, agriculture as a whole will benefit. We should make available to farmers dependable data on market prices, so as to enable them to take decision on the crops to be sown and on post-harvest sale of commodities. The APMC yards across the country are now being networked electronically by the Multi-Commodity Exchange of India (MCX), Mumbai. The National Commodities and Derivative Exchange (NCDEX), operates online trading through nearly 6000 terminals covering 33 agricultural commodities. 430 cities and towns across the country were covered be the exchange in Dec 2004. **It will be very useful if the Village Knowledge Centres are linked to NCDEX and MCX so that they can disseminate spot and futures price data among farmers.** It is also now possible to transmit such data on cell phones. We recommend that the Ministry of Agriculture may take speedy steps to bring this about.
1.11.0 Change in Mindset with reference to the role of the Ministry of Agriculture, Government of India

1.11.1 Several farmers’ organizations have suggested that the Ministry of Agriculture should be renamed as Ministry of Agriculture and Farmers’ Welfare.

1.11.2 We recommend the serious consideration of this suggestion since farmers’ well-being should be the main goal of the Ministry. This will also help to link faces with figures.

1.12.0 NDC Committee on Agriculture

1.12.1 We are happy that a NDC Committee on Agriculture has been set-up under the Chairmanship of Shri Sharad Pawar. We request that the suggestions contained in this Report as well as the earlier one may kindly be examined by the NDC Committee so that appropriate action can be taken concurrently at the Central and State levels.

1.12.2 The NDC Committee on Agriculture could also give consideration to the following

i) Mobilising financial resources from -
   a) Central Government
   b) State Governments
   c) Financial institutions
   d) Bilateral and Multilateral donor institutions

1.12.3 The order of additional investment needed for infrastructure development (production and post-harvest), capacity building and research and extension as well as the order of additional resources needed for doubling food production by 2010 will have to be calculated

ii) Indo-US Collaboration
   Some of the priority areas should be -
   a) Proactive land use advice based on reliable weather forecasts
   b) Assessment of soil micro-nutrient requirements using nano-technology
   c) Precision agriculture, to reduce cost of production and enhance income
CHAPTER 2
FOOD FOR ALL

2.1.0 Medium Term Strategy for Food and Nutrition Security with a view to move towards the goal of universal food security over time

2.1.1 The Mid-term appraisal of the Tenth Plan reveals that we are lagging behind in achieving the Millennium Development Goal of halving hunger by 2015. Under-nutrition and mal-nutrition are still widespread. Maternal and foetal under-nutrition is resulting in the birth of babies with low birth weight. This has serious consequences for the future intellectual capital of India. Therefore building a sustainable food and nutrition security system is an urgent task.

2.2.0 Food and Nutrition Security

2.2.1 The concept of food and nutrition security implies that -

i) every individual has the physical, economic, social and environmental access to a balanced diet that includes the necessary macro- and micro-nutrients, safe drinking water, sanitation, environmental hygiene, primary health care and education so as to lead a healthy and productive life.

ii) food originates from efficient and environmentally benign production technologies that conserve and enhance the natural resource base of crops, farm animals, forestry, inland and marine fisheries.

(Science Academies Summit, MSSRF, 1996)

2.2.2 This comprehensive definition of food and nutrition security provides guidelines for developing an effective operational strategy for achieving the goal of freedom from hunger.

2.2.3 Hunger has three major dimensions:

i). Chronic or endemic hunger resulting from poverty-induced undernutrition.

ii). Hidden hunger arising from micro-nutrient malnutrition, caused by the deficiencies of iron, iodine, zinc and Vitamins in the diet.
iii). Transient hunger caused by seasonal fluctuations in food availability and disruptions in communication and transport arising from natural or man-made disasters.

2.2.4 A sustainable national nutrition security system should cover all these three categories of hunger. It must also address the three issues of availability, access and absorption.

i. **Availability** of food at the household level depends upon (a) food production, changes in existing food grain stocks and / or imports.

ii. **Access** to food depends on livelihoods / purchasing power.

iii. **Absorption** of food is influenced by access to clean drinking water, environmental hygiene and primary health care.

In recent years, there is cause for concern on all the three counts of food availability, food access and food absorption.

2.2.5 Food Availability

2.2.5.1 In the nineties, food grain growth rate has slowed down drastically to 1.7 % and has fallen below the population growth rate of 1.9 %, so that per head annual net food grains output has fallen by about 3.5 kg from a peak of 180 kg. in the three years ending in 1994-95 to, 176.5 kg. by the three-year period ending in 2000-01. (Utsa Patnaik, [www.macroscan.org](http://www.macroscan.org), August, 2002 )

2.2.5.2 The decline in per capita food grain availability and its unequal distribution have serious implications for food security in both rural and urban areas.

2.2.5.3 In 1999-00, the average calorie consumption of a consumption unit in urban areas was 2637 kcal/day and this is not much higher than the norm of 2100 kcal/day, set for an urban adult. It is also important to note that while there are visible signs of an enormous increase in conspicuous consumption by the urban rich, there are also signs of increasing inequality in urban areas: in 1999-00, the bottom 10 percent of urban population obtained on the average only 1890 kcal/ day. That is, nearly 28 million people in our urban areas have unacceptably low levels of calorie consumption. (Food Insecurity Atlas of Urban India, MSSRF-WFP, 2002)

2.2.5.4 Similarly, going by the official Planning Commission estimate of the proportion of population below the poverty line of 27.09 percent in rural areas and 23.62 percent in
urban areas, a total of 260.27 million people in both rural and urban areas put together can be definitely assumed to be unable to buy sufficient food to achieve food and nutrition security. These estimates have been contested and can best be taken as the lower bounds of the estimated poor population in the country. The problem at hand is therefore of enormous dimensions. Besides, there are regional variations as well in the incidence of poverty. Across the nation, the poorest states are Orissa, followed by Bihar, Madhya Pradesh and Assam.

2.2.5.5 Though official data on poverty suggest a reduction in the percentages of population below the poverty line, there is reason for presuming that the incidence of hunger is increasing. Data on nutritional intakes suggest that income poverty is increasingly divorced from the calorie norm of 2400 kcal per consumption unit per day underlying the original official definition of poverty line. The data show that the percentage of population consuming diets providing less than 2400 kcal per capita per day is much higher now than the percentage below poverty line as estimated by the Planning Commission. Recent work by Professor V S Vyas suggests that in as many as eight major states, the proportion of the rural population accessing less than 1800 kcal/day (the level below which malnutrition can cause irreversible damage) exceeds 30 per cent. This is indeed cause for concern.

2.2.6 Food Access
2.2.6.1 Access to food grains is related to the purchasing power of the population and the nature of public distribution system that is prevalent. Purchasing power of large sections of the rural population has been weakened in recent years by the crisis in agriculture and rural livelihoods. In urban areas, the weakening of the PDS has exacerbated the problem of food insecurity.

(i) Rural Food Insecurity

Several studies have shown that the poverty is concentrated and food deprivation is acute in predominantly agricultural and rural areas with limited resources. Rain-fed agriculture is one of them. Agricultural labour and migrant labour are susceptible to hunger. In India of the 310.7 million rural workers, 103.12 million are agricultural labourers. Of these, about 48.37 million are females. Female agricultural labourers are
especially vulnerable to food insecurity on account of lower wages as well as the effects of migration.

One third of the rural work force is dependent on casual employment. This segment faces uncertainties of wage and work and is highly susceptible to food deprivation.

About 40.14 percent of the rural workers are cultivators. Of the total 124.68 million cultivators, about 40.64 million cultivators are women with inadequate resources and credit facilities. In hilly areas and rain-fed backward areas, often there are more female cultivators than male cultivators. Besides rural labourers, both agricultural and non-agricultural, small and marginal farmers also face food insecurity. Not only do they not get remunerative prices for their produce, they are also affected by the rise in retail/PDS food grain prices, being net buyers of grain.

ii) Urban Food Insecurity

It is often presumed that, since urban areas are covered by the PDS, food security is not a major issue in urban areas. This is not true. During the 1990s, the PDS has been weakened, both by repeated increases in the issue prices of food grains and by the switch to a system of targeted PDS. Besides, studies show that the bottom 10 percent of the urban population is not really helped by the prevalent system of PDS for accessing food grains. In 1999-00, average cereal consumption of bottom 10 percent of urban population was 9.55 kg/month in urban India. Of this, less than one kg/month was accessed from PDS (Food Insecurity Atlas of Urban India, MSSRF-WFP 2002).

This brings out the need to have a system of PDS that is flexible so as to ensure larger coverage. **People should be able to access grains from PDS whenever they want, wherever they want and in any quantity they want subject to a few ground rules to prevent purchase for hoarding and subsequent sale at high prices.** That is, flexibility with regard to time of purchase, place of purchase and quantity of purchase needs to be fitted in to the Public Distribution System. Accessing subsidized food grains is absolutely essential not only for the settled urban poor but also for the migrant population from villages.
As for purchasing power, the quality and quantum of employment of the population determine their income earning ability and therefore their ability to purchase food grains in the market. Casual employment normally fetches an income that is low and irregular; regular employment on a decent wage ensures a relatively better access to food. In 1999-00, in urban India only 4 out of every 10 workers belonged to the regular wage category; among the bottom 10 percent of urban population, nearly 4 out of 10 persons are casual labourers. The nature of the employment problem varies across different size classes of towns. Proportion of casual labour among males as well as females is much higher in small towns compared to the metropolitan cities or big towns. Similarly, the proportion of workers in regular employment is much lower in small towns compared to bigger towns. (Food Insecurity Atlas of Urban India, MSSRF-WFP, 2002)

Given the magnitude of the employment problem in urban India, particularly in the small towns, there is a strong case for a National Urban Employment Guarantee Programme.

2.2.7 Food Absorption

2.2.7.1 Biological absorption of food in the body is related to the consumption of clean drinking water as well as environmental hygiene.

The situation on this front is serious in India. For instance, in urban areas -

a) Slums that have inadequate facilities of sanitation and drinking water, provide shelter to nearly 22% of urban population in the country. In the early nineties, one third of slums did not have any drinking water facility and nearly half the slums did not have toilet facilities.

b) Access to basic amenities - safe drinking water, toilets, electricity, are much lower for households living in small towns.

c) In 1998-99, 15.4% of children were severely stunted and 11.6% were severely underweight.

d) While there are wide variations in the nature and extent of the problem of food insecurity across urban areas, small towns are especially vulnerable.

2.2.8.2.1 A National Food Security System should therefore give concurrent attention to the landless poor in villages and to casual and migrant labour families in urban areas, particularly in small towns.
2.3.0 Hunger-Free India: Components of Action Plan

A six-point Action Plan is suggested below for achieving the goal of Hunger-Free India.

2.3.1 Reform of the Delivery System: Restructure the delivery systems relating to all nutrition support programmes on a life cycle basis, starting with pregnant women and 0-2 infants and ending with old and infirm persons. An illustrative list of the programmes, which will benefit from a life-cycle based delivery system is given in Table 1. Elected Panchayats and local bodies should be involved in restructuring the delivery system.

Table 1: Current Status of Interventions

2.3.2 Community food security systems: Promote the establishment of Community Grain and Water Banks, involving Panchayats and local bodies. This programme should be based on the principle “store grain and water everywhere”.

2.3.2.1 The Community Grain / Food Bank system will help to widen the food security base by including a wide range of millets, grain legumes and tubers. While these can be operated by the nearly 240,000 Panchayats and Urban Local Bodies in the country, using flexible implementation mechanisms suited to local needs, the programme
should financially supported and regulated by the state to ensure social inclusion and sustainability.

2.3.2.2 The Community Foodgrain Bank (CFB) is a decentralized system of storage and management of food at the village level by the community to address the problems of difficulty in physical access to food due to natural calamities, seasonal imbalances and lack of purchasing power.

2.3.2.3 **Steps Involved in Setting up CFBs:**

i) **Foodgrain Corpus:** The calculation of amount of foodgrain required to be stocked is as follows:

The Indian Council of Medical Research (ICMR) norm of per capita per day cereal requirement by an adult is 420 grams. A family of 5 will therefore require 2100 gms per day, say 2 kg/day (assuming children in the household whose requirement will be slightly less). Extrapolating, the monthly requirement for a family is 60 kg and for a village with 100 households, the monthly requirement of foodgrains is 6 tons.

The ICMR norm for pulses is 40 gms per capita per day. For a family of five, this amounts to 200 gms per day and 6 kg per month. The monthly requirement of pulses for a village with 100 households is 600 kg.

The amount to be stocked has to be calculated on the basis of population needing assistance and period for which it is to be provided.

ii) **Storage Structure:** Storage is an important aspect needing attention. The storage space / structure will be determined by the amount to be stocked. It should be all weather resistant, located in a common place and accessible to all. The extant Community Grain Bank scheme of the Government of India unfortunately does not pay much attention to storage.

The requisite expertise for building the infrastructure for grain storage is available with the Indian Grain Storage and Management Research Institute of the Department of Food, as well as with Tata Steel Rural Development Society (TSRDS). The TSRDS has developed steel silos made of pre-fabricated steel that can be placed in the open and can withstand all weather conditions. These range in capacity from 1 m.t to 13 m.t. With guidance, they can be built locally by local self-help groups thereby generating employment.
iii) **Operation and Management:**

The initial corpus of foodgrains (rice and pulses to start with) is to be given free, based on the requirement. Subsequently, the mechanism should evolve into a community-managed bank wherein the members can borrow the cereals/pulses and develop a system of repayment in kind after a specified period at a pre-decided rate of interest, also in kind.

The system works like this:

a. Those in need of foodgrain can borrow foodgrain from the CFB. The eligible quantity will be determined with the ICMR benchmark as the norm.

b. The management of the CFB should be by the community. A food bank management committee of five to seven members, with at least 3 - 4 women, should be formed to monitor the operations. The village Panchayat will also be represented.

c. The period of loan, rate of interest all have to be decided by the committee in consultation with the entire village

d. Registers to be maintained: Stock Register, Lending and Repayment (Principal + Interest) Register, Individual Passbooks of Grain Borrowed and Repaid

2.3.2.4 Capacity building of the community to manage the CFB is very crucial. Sustainability of the mechanism hinges on ensuring livelihood security of the people.

2.3.2.5 Promote the growth of **community water security systems** based on a 5-pronged strategy consisting of:

i. **Augment supplies** through mandatory water harvesting and conservation

ii. **Give attention to demand management** by eliminating all sources of unsustainable use of water and promoting “more crop per drop” methodologies of crop cultivation

iii. **Harness new technologies** relating to improving domestic water use efficiency, desalination of sea water, breeding of drought and salinity tolerant crop varieties, bioremediation, etc.
iv. To begin with, each district in the country could develop a sustainable water security system. Community action should however start at the village level.

v. Promote seawater farming through integrated agro-forestry and aquaculture production systems in coastal areas.

vi. Pay attention to water quality. The quality of drinking water is deteriorating due to pesticide and bacterial contamination in ground water. Equal attention should be paid to the improvement of drinking water quality and the augmentation of water supplies. Bioremediation techniques will have to be used for removing arsenic and heavy metals from tube well water.

**Box 1**

**Community Food Banks in Orissa: A Success Story**

Community Food Banks, set up as models by the M S Swaminathan Research Foundation (MSSRF) with support from the World Food Programme (WFP), are in operation in eight tribal villages in the Koraput-Kalahandi region of Orissa. These villages vary in size from a hamlet with 9 households and a population of 54, chosen because of its difficult access, and a village of 127 households with a population of 529. Starting in 2002, the foodgrain corpus in all the project villages has increased by over 100 percent through repayments and voluntary addition to the stock by the community. There is no default. The Food Banks are managed by Food Bank Management Committees of 5 – 7 members. 50 percent of members are women. The Committee decides on the terms of repayment, interest etc. Community Seed Banks are also in operation in all the villages.

The functioning of the community food banks has led to several other positive outcomes. Besides a decline in food scarcity and insecurity, there has been a decline in the extent of migration in search of work, dependence on moneylenders, consumption of seed during crisis, and distress sales of produce. The old, infirm and destitute in the community are receiving greater attention and care now than was the case earlier.

Self Help Groups formed in the project villages have undertaken income generation activities like mushroom cultivation, vegetable, vermicomposting, poultry and fishery. As on March 2005, total savings in the bank of the SHGs was Rs.1,09,000. The SHG members had cumulatively availed loans to the extent of Rs.2,41,000 for income generation activities. Village development committees have also been formed in all the villages. Community development activities such as promoting health and sanitation awareness, maintaining a medicinal plants garden and micro-watershed development have been taken up in some of the villages.

The Orissa experience of MSSRF-WFP initiative shows that while an universal PDS, funded and managed by the State is absolutely essential to food security, it needs to be supplemented with locally managed food security systems in areas difficult to access. It must also be mentioned that a key factor underlying the success of the Orissa initiative is the cohesive nature of the tribal societies involved with the project.

2.3.3 *Eradicate hidden hunger* caused by micronutrient deficiencies based on natural food cum food fortification approaches. For example, salt fortified with iron, iodine, minerals and vitamins, coupled with the consumption of beta-carotene rich sweet potato
or vegetables will be very helpful to fight hidden hunger. Local SHGS can be trained to make nutritious biscuits as an income earning activity. Nutritional literacy should be promoted at the school level. High priority should go to the elimination of iron deficiency anaemia among pregnant women.

2.3.4 New Deal for the Self-employed

2.3.4.1 The unemployment rate on current daily status was about 9.21 percent (34.85 million) in 2001-02 in rural areas. Unemployment among rural youth increased from 9 percent in 1993-94 to 11.10 percent among males and 10.60 percent among females in 1999-2000.

2.3.4.2 Rural employment grew at 0.67% and agricultural employment at 0.02% during 1999-2000. According to the 55th round of survey of NSSO the share of self-employed in 1999-2000 was about 53%. The share of self-employed in total employment, 58% (133 to 134 million) was in the primary sector, i.e., agriculture and allied activities.

2.3.4.3 Detailed analysis of the causes of food insecurity in rural and urban India have revealed that inadequate purchasing power due to lack of job/livelihood opportunities is now the primary cause of endemic or chronic hunger in the country. Since opportunities for employment in the organized sector are dwindling, we have to create a policy environment that enlarges opportunities for remunerative self-employment in rural India in order to avoid an era of jobless economic growth.

2.3.4.4 Agriculture, comprising crop and animal husbandry, fisheries, forestry and agro-forestry and agro-processing, is the largest private sector industry in India, providing livelihood opportunities for over 600 million women and men. There is need to intensify efforts to create more opportunities for gainful livelihood opportunities in both the farm and non-farm sectors. According to FAO, malnutrition is high in areas where a very high percentage of population depends solely on agriculture for their livelihood. One reason for the high prevalence of hunger in villages is inadequate growth in opportunities for remunerative non-farm employment.

2.3.4.5 The menu of income earning opportunities for the self-employed needs to be enlarged. This calls for a paradigm shift from micro finance to livelihood finance. NCF had recommended in its first report that all the existing Krishi Vigyan Kendras (KVKs)
should be provided with a post-harvest technology wing. In addition, there is an urgent need for at least **50 SHG capacity building and mentoring centers** in every State, to enhance the management and marketing capacities of Members of the SHGs. Such centers can be established in existing institutions like Agricultural, Rural and Women’s Universities, IITs, institutions operated by NGOs, etc. Village Knowledge Centres can provide SHGs with e-commerce facilities. Accounting software will have to be introduced. SHGs will be sustainable in the longer term only if they have backward linkages with technology and credit, and forward linkages with management and marketing. Sustainable Self-help Groups (SSHGs) will emerge only if we build the capacity of the key members (both women and men of SHGs). **The SHG Capacity Building and Mentoring Centres** may be financially supported by the Union Ministry for Rural Development. This should be an essential component of the New Deal for the Self-employed.

### 2.3.5 Enhancing the Productivity and Profitability of Small Holdings:

2.3.5.1 Nearly 80% of the land holdings in India are below 2 ha in size. Unlike in industrialized countries where only 2 to 4% of the population depends upon farming for their work and income security, agriculture is the backbone of the livelihood security system for 2/3 of India’s population. **Therefore, farmers constitute the largest proportion of consumers.** The smaller the farm, the greater is the need for marketable surplus in order to get cash income. **Hence, improving small farm productivity, as a single development strategy, can make the greatest contribution to the elimination of hunger and poverty.**

2.3.5.2 Indian soils are both hungry and thirsty. Hence, soil health enhancement and irrigation water supply and management hold the key to the enhancement of small farm productivity. The following steps are urgently needed.

i. National network of advanced **soil testing laboratories** with facilities for the detection of micronutrient deficiencies. **As a single agronomic intervention, supply of the needed micronutrients in the soil has the greatest impact on increasing yield.** Hidden hunger is as widespread in soils, as in human beings. In fact, the two have causal relationships.
ii. Million Wells Recharge Programme

iii. Restoring Water bodies and promoting mandatory water harvesting.

iv. Establishment of 50,000 Farm Schools to promote farmer-to-farmer learning.

v. Organisation of Small Farmers’ Horticulture, Cotton, Poultry, aquaculture and other Estates, to promote group farming and to confer the power of scale to small producers both at the production and post-harvest phases of farming.

2.3.5.3 Farming is becoming a gamble both in the monsoon and the market and hence small farmers urgently need proactive advice on land and water use. Land use decisions are also water use decisions. The Every Village a Knowledge Centre Movement can help to give farmers dynamic advice on meteorological and marketing conditions.

2.3.5.4 In addition to dynamic advice, farmers also need proactive advice on land and water use. For this purpose, State Land Use Boards should be restructured, retooled and reactivated on the lines indicated in Fig 1. This is a task of the utmost priority.

2.3.5.5 We suggest that under the recently concluded agreement for cooperation with the United States in the field of agriculture, the following areas may receive priority.

i. Short and Medium term weather forecasting, in order to assist Land Use Boards to give proactive advice to farmers on crop and varietal choice.

ii. Rapid and low cost soil testing technologies based on nanotechnology. This will enable the application of need based macro- and micro- nutrients. Factor productivity in relation to fertilizer application is low now and this enhances the cost of production. The average fertilizer response of food grain output to NPK utilization works out to 7.8 kg. grain per kg NPK. This is a very low return.

2.3.5.6 Unless factor productivity is increased, small farm agriculture will become unremunerative. This is one of the causes for a high percentage of farmers wanting to quit farming. We must recognize the need for increasing the productivity and profitability of small and marginal farms, in order to eliminate endemic and hidden hunger in the families such farmers.

2.3.6 Designing and introducing a Food Guarantee Act:

2.3.6.1 We have over a century of experience in organizing relief work, under the provisions of the Famine Code in the colonial period, and Food for Work programmes in the post-independence period. It is clear that our agriculture has reached a stage when
farmers will grow more only if we can consume more. Hence, a **National Food Guarantee Act**, combining the features of the Food for Work and Employment Guarantee Programmes, will represent a win-win situation both for producers and consumers. Women, in particular, prefer a combination of grains and cash as wage, provided the food grains are of good quality.

2.3.6.2 A **National Food Guarantee Act** should lead to a decentralized network of grain storage structures and thereby help to prevent panic purchase of food grains during periods of drought or flood. They will also help to prevent distress sales by producers at the time of harvest. In addition, it will help to enlarge the composition of the food security basket.

2.3.6.3 Brazil, Kenya and a few other countries have announced, “Zero Hunger” programmes. **India can take the lead to give meaning and content to the zero hunger concept by developing a National Food Guarantee Act.**

2.3.6.4 The major features of a National Food Guarantee Act were discussed at a Consultation held at MSSRF on 19 June 2005. The participants made the following suggestions:

1. The main aim of the proposed legislation should be to integrate the features of Employment Guarantee Acts (National and Maharashtra) and Food for Work Programmes, in order to ensure that every child, woman and man has physical, economic, social and environmental access to balanced diet, clean drinking water and primary health care. This is fundamental to providing every individual in the country an opportunity for a healthy and productive life. Rural and urban populations as well as migratory labour families will have to be covered. Social inclusion should be the bottom line.

2. The National Food Guarantee Act should be gender sensitive. The concept of “work” should be enlarged to cover also skilled work related to human and social development, as for example, establishing and running crèches, balwadis, preparing noon meals, etc.

3. Payment of a part of the wage in the form of food grains has the double advantage of helping farmers in the area of marketing, and consumers in the form of obtaining their basic caloric requirements in the form of good quality food grains
at a reasonable price. This will also help to enlarge the composition of the food security basket.

4. Food guarantee can become a reality only if there is an implementation mechanism characterized by low transaction cost, transparency and freedom from corruption. The Gram Panchayats / elected local bodies may be able to provide such a mechanism. The Gram Panchayat / Local Body can form in the respective villages a Consortium of Agencies like SHGs, Mahila Mandalas, Farmers’ Clubs etc, to provide oversight to the implementation of the integrated food for work and employment guarantee approach to the elimination of hunger and poverty.

The Panchayat can thus provide a platform for partnership at the grass root level. However Panchayats will need the necessary legal, financial and technical empowerment. There are a large number of tasks, which are assigned by Constitution Amendment 73 to Panchayats, but they have no capacity to discharge these responsibilities since they have not been legally or financially empowered to do so. Capacity building of women and men Panchayat members in undertaking such tasks has to proceed concurrently with financial empowerment.

5. Information empowerment on entitlements is vital for success. Household entitlement cards can be distributed and full use could be made of Mission 2007: Every Village a Knowledge Centre Programme. The recently enacted Right to Information Act will also facilitate the process of empowering the rural poor (often illiterate) in understanding their entitlements under various pro-poor schemes of Central and State Governments.

6. Training and Capacity Building of all concerned with the implementation of the programme is extremely important. Suitable institutions will have to be identified for imparting training to administrators, Panchayat leaders, SHGs and others who will be involved in implementing the Food Guarantee Act.

7. The Act should provide scope for including feasible land reform measures like providing dalits and the poor with space for a homestead garden where the needed vegetables and fruits can be grown. SHGs can also be given space on lease in common property land for raising nutrition gardens and fodder for farm animals.
8. Integration with primary health care is exceedingly important. For example, de-worming should be made compulsory at least once in two months. Multiple fortified salts could be used in noon meal programmes in order to attack the problem of hidden hunger caused by micro nutrient malnutrition.

9. The Act could stimulate a movement for storing grain and water everywhere through community food and water banks. A national network of community food banks could be established.

10. Nutrition and education are fundamental to enabling every individual to experience a productive and healthy life. Therefore the enactment of a Food Guarantee Bill will be the best method of ensuring that we are able to accomplish the UN Millennium Development Goals.

11. Thanks to the extensive work done both within the country and outside on issues relating to “Right to Food”, there is considerable legal and technical expertise available for preparing a framework for Food Guarantee. We should therefore proceed with this initiative.

12. It will be appropriate to operationalise the Food Guarantee Act on August 15, 2007, which marks the 60th anniversary of India’s independence.

### 2.4.0 Road Map for Eliminating Hunger

2.4.1 In summary, the six-point action plan recognizes that the problem of food security is both multidimensional and cuts across the rural-urban divide. Since urban food insecurity and deprivation are closely related to rural deprivation, a comprehensive rather than a sectoral approach is required.

The six points in brief are:

1. Reorganise the delivery of nutrition support programmes on a life-cycle basis with the participation of Panchayats and local bodies.

2. Eliminate micronutrient deficiency induced hidden hunger through an integrated food cum fortification approach.
3. Promote the establishment of Community Food and Water Banks operated by Women Self-help Groups, based on the principle “Store Grain and Water Everywhere”.

4. Help small and marginal farmers to improve the productivity and quality of farm enterprises.

5. Introduce support systems to SHGs to make them economically and organizationally sustainable. Establish for this purpose SHG Capacity Building and Mentoring Centres and focus on Livelihood Finance.

6. Formulate a **National Food Guarantee Act** continuing the useful features of the Food for Work and Employment Guarantee programmes and introduce it on 15 August, 2007, which marks the 60th anniversary of our independence. The Food Guarantee Act will be a powerful tool in achieving the goal of a hunger-free India. By increasing demand for food grains as a result of increased consumption by the poor, the economic conditions essential for further agricultural progress can be created.

---

**Proactive Advice on Land use**

(Land use decisions are also Water use decisions)

**State Land Use Board**

(to be located in an Agricultural University)

Integrated advice

- Meteorological Factors
- Ecological Factors
- Marketing Factors (Home and external markets)

The Land Use Board through a virtual college should give proactive advice on the choice of crops and farming systems, so as to achieve a match between demand and supply in farm commodities and to ensure that the most efficient crops are grown in different agro-climatic and agro-ecological regions.
CHAPTER 3
FISH FOR ALL

3.1 The Terms of Reference of the National Commission on Farmers (NCF), inter-alia provide; “Suggest measures to attract and retain educated youth in farming and recommend for this purpose; methods of technological upgrading of crop husbandry, Horticulture, Animal Husbandry; Fisheries (Inland and Marine), Agro Forestry, Agro processing and associated marketing infrastructure” etc.

3.2 Chapter V of the First Report of the NCF has already dealt with the subject of Horticulture and the subject of Marketing has been discussed in Chapter V of this Report. The subject of Fisheries (Inland and Marine) is discussed in the following paragraphs.

3.3 Fisheries, both inland and marine offer great scope for income generation and nutritional security for the people and export opportunity for the country. More than seven million fishers directly and an extremely large number of people indirectly are dependent on Fisheries for their livelihood.

3.4 The Tenth Five Year Plan had targeted GDP growth in agriculture and allied sectors at 4 per cent per annum. The actual growth during the first three years of the Tenth Plan is only 1 per cent per annum. In contrast, the growth rate in fisheries sector had been sustained at 4.3% during the Ninth Plan, because of the untapped potential being exploited particularly through aquaculture. It is felt that the greater attention to fisheries through higher investment proposed in this Chapter would help to further increase the growth rate of fisheries sector. A growth of 8% in the fisheries sector would be needed to help in the achievement of a 4% growth in agriculture.

3.5 The Tenth Five Year Plan envisages increasing fish production from 62 lakh tonnes in 2002-03 to 82 lakh tonnes in 2006-2007, with a financial outlay of Rs.740 crores in the Central and Rs.1324 crores in the State plans. This requires a focus on sustaining gains already made in production; protecting the productivity of inland and marine fisheries, increasing production through expansion of area and new technical breakthroughs; adding value to the produce and ensuring quality; and creating increased livelihood avenues through remunerative and assured marketing opportunity.
3.6. India’s strategy for attaining the objective of “FISH FOR ALL” is:

- **Enhancing** productivity in all inland ponds and achieving sustained high production per cubic volume of water in them; giving integrated attention to capture and culture fisheries both in inland ponds and in coastal areas.

- **Ensuring** the adoption of responsible and sustainable fishery practices in the area of marine fisheries and introducing a code of conduct for this purpose.

- **Establishing** agro-aqua farms, involving the cultivation of mangroves and *Salicornia, casuarinas*, cashewnut, coconut and other appropriate tree species and the culture of prawns and shrimps.

- **Spreading** quality literacy among fisher families with reference to sanitary and phytosanitary measures and codex alimentarius food safety standards.

- **Improving** facilities for fish landing, storage, transportation, processing and marketing.

- **Developing** social marketing techniques, which can help to ensure the availability of good quality aquatic products to resource-poor consumers.

- **Introducing Aquarian Reforms** to help in the spread of fish enterprises based on the principle of environmental sustainability, economic viability, social, general equity, nutritive quality and food safety. Aquarian Reforms should aim to promote harmony between artesenal and mechanised fishers and Agriculture and Aquaculture and cover both Indian and coastal water resources.

- **Organising Fish for All** training centres for fisher families based on the principle of learning by doing, to impart latest technical skills ranging from capture or culture to consumption. Helping both resource poor producers and resource poor consumers through sustainable self-help groups is a major objective of the “Fish for All” programme.
A Summit was organized by M.S. Swaminathan Research Foundation with World Fish Centre (ICLARM), Government of India and Government of West Bengal in Kolkata on December 18-19, 2003 for the National launch of “Fish for All”. The objective was to ensure “Fish for All and Forever” and the Summit sought to develop a road-map for achieving this goal by 15th August, 2007 which marks the 60th anniversary of India’s independence. To achieve the objectives, the Action Plan “Agenda 2007” was formulated as under:

<table>
<thead>
<tr>
<th>I. Public Policy and Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Through <strong>Aquarian Reforms</strong> ensure productivity, sustainability, profitability, gender and social equity in capture fisheries (marine and inland), aquaculture and non-food fisheries (e.g. sea weeds);</td>
</tr>
<tr>
<td>• Set up a separate <strong>Ministry/Department of Fisheries</strong> in the Union Government and bring aquaculture and fisheries on par with agriculture especially in the provision of basic infrastructure needed for the sector;</td>
</tr>
<tr>
<td>• Formulate a National Fisheries Policy for sustainable development taking in to account the needs of the fisheries and aquaculture sectors as well as opportunities for domestic and international trade;</td>
</tr>
<tr>
<td>• Strengthen existing fisheries legislation both at center and the states; and formulate new legislation where necessary in order to help in realizing the full potential of the sector to improve nutrition and provide more jobs and income;</td>
</tr>
<tr>
<td>• Policy on water allocation for freshwater fish culture on par with irrigated agriculture; allocation of specific areas for women enterprises;</td>
</tr>
<tr>
<td>• Reduce post-harvest losses and increase value by launching intensive Quality and Scientific Literacy Movement through use of modern ICT technology, sanitary and phytosanitary measures and globally accepted standards on hygiene and sanitation;</td>
</tr>
<tr>
<td>• Legislation on introduction and control of exotic species.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>II. Implementation of Programs for Sustainable Development</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Regulate and limit access through implementation of monitoring, control and surveillance of fisheries;</td>
</tr>
<tr>
<td>• Conserve and sustainably exploit marine resources through harmonized seasonal ban on fishing across maritime states; elimination of destructive fishing; declaration of closed areas and setting up of sanctuaries;</td>
</tr>
<tr>
<td>• Deploy effort in less exploited areas (e.g. harnessing offshore marine resources, sea weed culture, etc.)</td>
</tr>
<tr>
<td>• Set up small-fisher aquaculture estates to bring in social equity. Estates to have backward linkages with R&amp;D institutions and forward linkages with assured and remunerative markets;</td>
</tr>
<tr>
<td>• Organise National Pilot Projects for demonstration of new technologies such as sea water farming for prosperity of coastal areas; setting up of bio-villages for providing sustainable livelihood opportunities; low external input sustainable integrated farming practices, culture of ornamental fishes, etc;</td>
</tr>
<tr>
<td>• Implement national level programs for reduction of post-harvest losses and popularisation of low-cost value addition technologies;</td>
</tr>
<tr>
<td>• Develop strong domestic marketing infrastructure.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>III. Strengthening of Institutional Mechanisms and Capacity Building</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Set up a professional–managed <strong>National Fisheries Development Board (NFDB)</strong> for overall fisheries and aquaculture development;</td>
</tr>
<tr>
<td>• Strengthen existing institutional mechanisms and census information for implementation of developmental programs;</td>
</tr>
<tr>
<td>• Strengthen existing fisheries education institutions and set up a national facility on the model of the Indian Institute of Technology for harnessing the opportunities provided by space, information and communication technologies as well as biotechnology and renewable energy technologies.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>IV. Public Awareness</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Implement programs for bringing awareness among public and policy makers on the need for conservation and development of aquatic resources, sustainable and responsible fisheries and aquaculture, including adoption of good management practices;</td>
</tr>
<tr>
<td>• Create awareness on safety issues among small-scale fishermen;</td>
</tr>
<tr>
<td>• Create awareness on the contributions of fish to nutritional security.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>V. Partnerships</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Develop bilateral, regional and international collaborations to strengthen the functioning of research and development institutions in the country.</td>
</tr>
</tbody>
</table>
3.7 There have been several major positive developments over the years, which have the potential to develop Fisheries to the optimum level. The Government of India have already formulated a Marine Fishing Policy in 2004. They have also adopted the FAO’s Code of Conduct of Responsible Fisheries and have very recently enacted Coastal Aquaculture Act, 2005. India is also a Member and host for Bay of Bengal Programme inter-governmental Organisation (BOBP-IGO) whose work for safety, responsible fisheries and small fisher marketing as well as simple post harvest technology have been commendable.

3.8.0 SWOT Analysis for the Fisheries Sector in India

3.8.1 It would be useful to conduct a SWOT analysis in order to appreciate the potential for employment, income generation and nutritional security for the people, while making Indian fisheries globally competitive.

3.8.2 Strengths

i. India has vast inland and marine water resources. We have 2.3 million hectares of fresh water tanks and ponds, 1.3 million hectares of oxbow lakes and derelict waters and reservoirs with water spread of 3.1 million hectares.

ii. Further, we have 1,91,024 km of rivers and canals system. Besides we have 1.2 million hectares of brackish water resources.

iii. India has an Exclusive Economic Zone (EEZ) of over 2.02 million sq. m with the continental shelf of about 0.51 million sq. km and a coastline of 8118 kms (3600 fishing villages) besides, our large coastline has substantial area under estuaries, lagoons and backwater, which harbour a variety of fin and shellfish resources.

iv. Further, India is blessed with a large variety of agro climatic zones extending from the very cold regions in the Himalayas to the temperate regions in the South for inland fisheries. Both saline water as well as fresh water resources are available.

v. India has also one of the richest and well-diversified fish fauna in the world.

vi. Since India is largely located in tropical and sub-tropical zones, the biological productivity of its aquatic resources is also very high. This could be utilized to have a broad based fisheries sector for the diverse conditions in the country.
vii. India has a well-established system of fisheries research and education through ICAR institutions focused on specific fisheries sub-sectors: Central Institute of Fresh Water Aquaculture, Bhubaneswar, Central Inland Fisheries Research Institute, Barrackpore and Central Institute of Brackish Water Aquaculture, Chennai, focus on inland fisheries. Central Marine Fisheries Research Institute, Kochi; Fisheries Survey of India, Mumbai, Central Institute of Coastal Engineering for Fisheries, Bangalore and Central Institute of Fisheries and Nautical Engineering and Training, Kochi, focus on other specific sub-sectors while Central Institute of Fisheries Education, Mumbai concentrates on Human Resource Development for Fisheries. In addition, there is a National Research Centre on Cold Water Fisheries, Bhimtal and National Bureau of Fish Genetic Resource, Lucknow. These are being supplemented by the large number of Agricultural Universities with Colleges of Fisheries. This research and training infrastructure must provide technological backup to fishers for more productive and sustainable fisheries through optimum utilization of available water resources. Marketing and export promotion is further assisted by Marine Products Export Development Authority (MPEDA) and National Cooperative Development Corporation (NCDC)

viii. Fisheries is a well-established activity in many parts of the country and the traditional knowledge and the expertise of the fishers has the potential to be utilized for bigger and more sustainable harvest through proper training and technological support.

ix. India has one of the best fish-processing infrastructures in the world, which is currently under utilized due to shortage of raw material.

3.8.3 Weaknesses

i. Through years of neglect, the water bodies particularly river systems in the country have faced massive pollution level arising out of increased and unrestrained industrial activity. This has recently affected the fisheries resources particularly in the rivers. Similarly, marine resources have suffered due to pollution arising out of unsustainable activities in the coastal regions and
inadequate attention to pollution due to off shore oil exploration and shipping. There has been inadequate awareness generation and insufficient technology dissemination.

ii. Due to unsustainable activities particularly in the Himalayas, there has been substantial soil denudation leading to heavy silting of the rivers system leading to shrinkage of water bodies.

iii. There has been inadequate attention to maintenance of water bodies like ponds, floodplain lakes (beels) etc., and even recently constructed reservoirs and ponds/tanks have reduced capacity for stocking of fish due to growth of water hyacinth etc.

iv. Quality control for fish seed as well as fish feed is virtually non-existent leading to malpractices and exploitation of the fishers. Further, there is reliance only on a few species. This has dangerous repercussions.

v. Post harvest losses in the marine sector are as high as 30 per cent due to constraints of fishing fleet bed on shore handling and poor marketing facilities.

vi. Open access regime due to population pressure both for inland and marine fisheries leads to reduced catches per unit effort and uncompetitive production.

vii. Multi-user conflicts and excess extraction of water for multifarious uses lead to depletion of fish stocks.

viii. Neglect of reservoirs at the pre-impoundment and impoundment stages leads to inefficient exploitation of this vast resource.

ix. Unsustainable and unscientific leasing policy leads to poor utilization of resources.

x. Database on resources as well as production/yield levels creates difficulties for policy formulation.

3.8.4 Opportunities

i. Fisheries are an excellent source for nutrition particularly for protein. White meat particularly fish is preferred by the health conscious people over red meat globally. There is thus an adequate market for higher quantities/varieties of fish both nationally and globally.
ii. Considering India’s huge population, the size of the domestic market itself offers great incentive for higher production and technologies are available both nationally and internationally for optimum utilization of aquaculture, both fresh water and brackish water, for enhancing production sustainably. Approximately 60% of our population is fish eating.

iii. Many countries have over-fished their marine resources and now offer a large market for produce from India.

iv. Developed countries take up 85% of total imports of fishery products. Global trade is of the order of US $ 56 billion.

v. India has produced and is exporting Tiger shrimp (\textit{P.monodon}), which enjoys a premium market abroad in view of its size and taste. In marine fisheries, India alongwith Maldives produces yellow fin tuna, which is a premium variety internationally.

vi. Indian rivers particularly in the Himalayas and Cauveri in the South have excellent game fisheries of Mahseer. Through appropriate stocking of Mahseer and Rainbow trout, sport fisheries provide an excellent means of promoting tourism.

vii. Entire Himalayan region, which is relatively unpolluted eco-system, is under exploited in terms of cold water fisheries.

3.8.5 Threats

i. India’s neighbours, particularly China, have gone in for large-scale production of \textit{P.vannamei} through domesticated brood stock. Compared to this, India’s Tiger shrimp production is still dependent on wild brood stock. Requirement of protein for \textit{P.vannamei} is also less, making it cheaper to produce. China and other South Eastern countries produce large quantities of \textit{P.vannamei}, and offer stiff competition for Tiger shrimp in the market abroad.

ii. There is an absence of well-equipped fish health laboratories and competent extension centres, to advise aquaculture fishers about, fish health and treatment.
iii. The infrastructure, particularly for marketing, is poor and the facilities for maintenance of hygiene and good value realization in the fish markets are deficient.

iv. The infrastructure for marine capture fisheries is also inadequate going by the size of the fishing fleet. The harbours and fish landing centres suffer from inadequate facilities for hygienic landings, cold storage and cold chains availability and poor handling. All these constraints lead to poor value realization by the fisher and also may create problems for exports in view of sanitary requirements.

v. The technology for processing at fisher level is still not widely used. This leads to large-scale spoilage and the fishers are denied the benefit of value addition.

vi. People all over the country have not yet developed the taste for processed marine fish and, therefore, there is inadequate domestic market for processed marine fish.

All told, the strengths of the fisheries sector coupled with opportunities have a great scope of promoting livelihood and providing nutrition. India has the capability of taking care of the weaknesses and the threats to improve its position as the fourth largest fish producer, and second largest producer in Aquaculture globally. We have to proceed in the directions of greater productivity, better diversification, sustainable practices, hygienic handling at all stages comprehensive infrastructure and above all skill upgradation and human resource development.

### 3.1.0 Inland Fisheries

#### 3.1.0 An overview

3.1.1 The vast and varied inland waters (viz. lakes, reservoirs, wetlands, rivers, streams, ponds and tanks) constitute an important fisheries resource of the country. In recent years, the fish production from these open and confined waters has increased considerably reaching to a current level of 3.4 million tonnes- accounting for 53.12% of the country’s fish basket. Notwithstanding this marked achievement, the traditional fishers have gained little in stature and income out of the fisheries development and concerns on the economic condition of fishers persist. These concerns become more important in the context of rising environmental degradation, depressed prices world
over, emerging new economic order following WTO and signing of several multilateral agreements. Further, despite generation of considerable baseline information and technologies by the national institutions/universities, the country’s cumulative fish production is hardly commensurate with the nation’s water resources and decidedly far below the inland fish production of China which is about ten times more than India.

3.1.2 Inland water resources harbour the original germplasm of one of the richest and most diversified fish fauna of the world, comprising 930 fish species belonging to 326 genera. The resources provide full time vocation to 1.2 million inland fishers, and yield 3.4 million tonnes of annual fish production. India is the second largest producer of inland fish in the world and the sector plays a great role in nutritional security and employment potential. Besides being a source of income and livelihood to poor fishers, it also engages the rural population in ancillary jobs such as marketing, retailing, transportation etc. The sector achieved a growth rate of 12.7% during 2002-03. However, the sector still remains largely unorganised even today mainly due to the scattered and diffused nature of activities.

3.1.3 During the past two decades, a shift has been observed from marine fisheries to inland fisheries. Fish farming of carps and crustaceans is likely to witness manifold increase in the coming years in view of its profitability. This would be possible only through diversification of cultural practices and enlarging the cultivable *ecotypes* including new species as well as cultural practices like fish-cum-pig culture, fish-cum-poultry, and paddy cum fish culture etc. The new unexploited areas also include rainbow trout farming, ornamental fisheries, fresh water pearl farming, farming in inland saline waters, backyard fish culture, air breathing fish culture, flow thru fish culture, algae culture etc. There are a few other challenges viz. multiple use of water leading to scarcity of water in future affecting aquaculture activities, large scale diversion and abstraction of water in view of emergence of new river valley projects, risks from diseases making bio-security a critical issue, availability of quality seed and fish feed etc. In particular, care should be taken by the State authorities in the interest of the ecology to discourage brick kilns from coming up near village ponds/water bodies, which harbour fish biodiversity/natural fish breeding.
3.1.4 The above challenges highlight the need for accelerating productivity through genetic improvement of brood stock, sustainability of production, better health management, water control/management, code of conduct for responsible fisheries, feed management, processing and value addition, fishery credit, legislation and strengthening of marketing infrastructure and extension machinery.

3.1.5 Though fisheries has been recognized as a thrust area in the country’s successive five-years plans, a clear-cut comprehensive fisheries policy is yet to be finalized.

3.1.6 In recognition of the increasing role of inland fisheries in overall fish production, the GOI is implementing several schemes including support to Fish Farmers Development Agencies (FFDAs)/Brakishwater Fish Farmers Development Agencies (BFDAs) programme for fish seed development, cold water fish culture, strengthening of inland marketing etc. A network of 429 FFDAs and 39 BFDAs cover all potential districts of the country. The fresh water area brought under fish culture till date is 6.5 lakh hectares benefiting 11.3 lakh farmers. Over 7.6 lakh unemployed youths have been trained in improved fishing practices. Additionally, about 0.14 million ha area has been covered under shrimp culture. Under the national programme for fish seed production, over 1070 (300 shrimps) fish seed hatcheries have been commissioned producing 20,000 million fish fry in the country during 1999-2000. However, out of the country’s resources only 16% of fresh water area and 10% of brackish water area is reportedly being utilized for fish culture. More comprehensive use of the untapped resource should be planned.

3.1.7 While the country has achieved record fish and seed production levels the variety and quality are still an area of concern. Over 80% of fish seed produced in the country belongs to three species of Indian major carp viz. Rohu, Catla and Mrigal or to some extent Silver Carp, Grass Carp or Common Carp, even though there are 46 species of fish and shell fish amenable to culture in the country. Barring a few trials undertaken by the ICAR institutes, standard large-scale seed production technologies of mahseer, hilsa, large catfishes, air breathing fishes, snow trout etc. are still elusive. The varied type of water resources and country’s agro-climatic conditions necessitate the availability of seed of these hitherto neglected fish species and bring them into culture arena.

3.1.8 There is an overall need to actively involve Panchayati Raj Institutions, Cooperatives, private sector, NGOs and Self Help Groups (SHGs), in the extension and
promotion programme. Instruments like seed, feed, credit, extension, R&D and database are critical. Certification of seed as well as feed by Government recognized agencies warrant priority attention.

3.1.9 A separate National level Agency coordinating with Research Institutions and providing requisite support to aquaculturists / entrepreneurs / corporate bodies is urgently needed and should be set up by restructuring the Central Institute of Fisheries Education, Mumbai.

3.1.10 Aquaculture is not treated at par with agriculture or industry. This is not only unjust but also a big impediment to the growth of fisheries. During mid 1990s, a decision to put fisheries at par with agriculture was taken in the Central Board of Fisheries meeting held under the Chairmanship of Union Agriculture Minister but later the decision was not implemented. It is high time that final decision to place aquaculture and artesenal fisheries at par with agriculture is taken. Fisheries rightly deserve parity with agriculture in view of several commonalities. In view of the dwindling catches in the rivers system and in the coastal fisheries due to various constraints, fisher folk can be weaned away into aquaculture sector very conveniently which would provide them sustainable employment and income and also relieve pressure on riverine and coastal fish resources. Since aquaculture offers immense scope for employment generation and export opportunities, it would be in the interest of the Government to encourage this activity by exempting small-scale aquaculturists and artisnal fishers from income tax by treating this activity as agriculture. Similarly they could lower the cost of production if they are offered credit at differential rate of interest, loan facility for tubewell, supply of water/canal water at concessional rates, supply of seed and feed at subsidized rates, supply of fertilizers at subsidized rates and subsidy on transport and acquisition of means of transport. Persons involved in agriculture enjoy these facilities and fishers who face similar risks and constraints should also get these benefits. It should be possible for the Department of Agriculture and Cooperation to work out the costs and benefits for extending these facilities to fishers by treating aquaculturist and artesenal fisheries activities as agriculture.

3.1.11 During the series of consultations held with the stakeholders/administrators and field workers, it emanated that many of the problems of fisheries, especially aquaculture,
could be solved and the sector can grow fast if an autonomous **National Fisheries Development Board (NFDB)** on the lines of National Dairy Development Board (NDDB) is set up in the country. The status of an autonomous body would provide much needed working freedom and momentum to the various programmes to benefit fisheries sector in general and fishers in particular. It should be a body with technical experts/professionals from different segments of the fisheries sector. The Board should do the handholding for the fishers from the production to the marketing stage, particularly for small fishers and be the friend, philosopher and guide for them. Above all the Board must adopt a single window approach so that the multiplicity of agencies/regulatory bodies/Ministries could be avoided. This is particularly necessary in the interest of the State Governments implementing various programmes and the fishers who are often unable to benefit from such programmes due to plethora of rules/ agencies. It would also avoid duplication and ensure flow of funds more effectively. While the Board should have representation at a very senior level from the various ministries/stakeholders, it should be supervised by an Advisory Committee headed by the Union Agriculture Minister. Needless to add, it is critical to have representative of the fisheries sector drawn from the inland and marine sector, women fisher folk, feed and seed producers, traders, exporters, vessel owners, processors and banks. The Board could also serve as an umbrella organization for a host of training institutions, which exist today but suffer from lack of cohesion and composite direction. It is however stressed that the Board should never degenerate into a body delivering subsidies only but must cover all activities relating to planning and implementation in collaboration with the States/Research institutions and the stakeholders. The Commission would be very happy to assist in the formulation of the scope of the Board. Since the Board has to be provided a very large and effective mandate, it must be provided adequate funds to serve as margin money so that it could also draw institutional finance for its revenue generating activities.

It is felt that a sum of Rs. 3500 crores up to the end of Eleventh Five Year Plan should be provided to the Board with 50 % as grant and the remaining as interest free, long-term loan. Considering that the Government has decided to step up public investment in agriculture, funds of this magnitude should not be difficult to find, especially in view of
commendable growth rate in fisheries sector vis-à-vis agriculture and the great opportunity for income from export.

3.1.2.0 Capture Fisheries

3.1.2.1 The capture fisheries resources of the country comprise of rivers, canals, estuaries, flood plains, wetlands, lagoons and reservoirs. The riverine systems comprise 14 major and 44 medium rivers, innumerable tributaries and branches. With a combined length of 45,000 kms and 20,000 sq. kms of catchment area, the country’s riverine resources provide one of the richest fish germplasm of the world. The flood plains are primarily continuum of rivers and exist in the form of oxbow lakes especially in the states of Bihar, West Bengal, Assam, Manipur and eastern Uttar Pradesh. Reservoirs constitute the single largest inland fishery resources both in terms of resource size and productive potential. As per FAO, the country has 19,370 medium and large reservoirs with water spread of 3.15 m ha.

3.1.2.2 Seven major rivers contribute to the estuarine resource of the country. Besides, a large number of smaller rivers on both the coasts also end up in estuaries. The largest and richest estuarine system in the country encompassing the Sundarbans, a complex of several estuaries is Hooghly-Matlah followed by Mahanadi, Narmada, Tapti and other peninsular estuaries.

3.1.2.3 The major river systems of India on the basis of drainage are divided broadly into two: (i) Himalayan River System (Ganga, Indus and Brahmputra) and (ii) Peninsular river system (east coast and west coast river system). The flood plains of Ganga and Brahmputra have the distinction of nurturing some of the finest wetlands of the country. The country has an estimated 2.0 m ha of flood plains lakes where fish and fisheries remain a traditional economic activity with tremendous socio-economic impact in the rural sector. The cold water fisheries resources of the country are comprised of rivers,
streams, lakes, reservoirs with combined riverine length of 8,310 kms and 43,770 ha of lakes and reservoirs. Besides, there are vast sheets of inland saline water located in different states of the country and largely unexploited.

3.1.2.4 After independence and ushering in of an era of industrialization, pressure on the water intensified and need for power, irrigation, flood control and waste disposal led to progressive destruction and shrinking of river water, their siltation and pollution with chemical and domestic discharges.

3.1.2.5 Despite the ‘Clean the Ganga’ programme the river Ganga is highly contaminated from Hardwar down to Diamond Harbour. The average fish yield has gone down from 27 kg/ha during 1958-61 to 3 kg/ha during 1999-2000. There is a significant change in the
catch spectrum coupled with reduction in size distribution of fish. The tributaries of the Ganga too are highly polluted and impacting its fisheries. Water abstraction owing to construction of dams has resulted in reduced flow affecting the migratory run of fishes. The increased pollution and silt load have further aggravated the problem of water quality and fish carrying capacities. Yamuna is perhaps much more polluted due to discharge of effluents. The fish catches have dwindled drastically and coarse, hardy, trash fishes have taken over the place once occupied by the commercially important Indian carps. Similarly the Brahmaputra with 20 tributaries on its northern bank and 13 on its south, is carrying more silt than water during its flow resulting in the rise of its bed and loss of breeding grounds. Mahseer, snow trout and minor carps dominate the catches. As for Mahanadi, catfishes, carps and mahseer/prawn dominate three different regions of the river. In view of emergence of number of impoundments, the Godavari has been reduced to the status of a trickling stream. The barrages built across the river have restricted Hilsa runs while the transplanted Indian major carp failed to develop into commercial significance.

3.1.2.6 Cauveri is a biodiversity hot spot in having a unique fauna of exotic and Indian carps, catfishes and minor carp. Flowing along the foothills of Himalayas, the rivers Ravi, Satluj, Beas and Chenab harbour precious varieties of cold water fishes viz. trout, mahseer, snow trout and other hill stream fishes. These upland rivers and streams are basically the cradles of cold water fishes and serve as nurseries and rearing grounds for commercially important fish species. Changes in riverine ecology due to water abstraction, dam construction effluents and domestic discharges have adversely affected the breeding, feeding and rearing grounds of the fishes. Rapid industrialization has further added the woe of pollution and sediment concentration.

3.1.3.0 Fisheries management

3.1.3.1 In view of fast ecological degradation, the scientific management of riverine fisheries has not been made possible. The Central Inland Fisheries Research Institute, Barrackpore, has monitored the catches at a few selected centers on the Ganga, Yamuna, Brahmaputra, Narmada and Godavari. With the construction of series of dams and resultant ecological changes in the riverine habitat, the catches are declining markedly
and posing a vocational threat to the traditional river fisher folk. This threat gets further compounded with the release of noxious industrial effluents and pesticides in these water bodies. The situation warrants immediate measures by taking active conservation programmes such as habitat restoration of select stretches of streams. Further, basin-wide approach with legal and institutional mechanism is imperative for reducing adverse interaction and conflicts between fisher and hydro power/industrial sector. Undertaking of Environment Impact Assessment Studies (EIA) for ascertaining project’s adverse impact of projects on fisheries needs to be made mandatory, prior to signing of new hydropower project agreements. Compensatory capture/culture fishing activities should be provided for those who lose livelihoods. This would be on the principle of compensatory afforestation. In areas where industrial pollution threatens local fisheries, the cost for controlling of chemicals or sediments for mitigating fish losses requires compensation. The States’ Fisheries Acts need suitable revision with a provision under which polluters must pay the damage cost.

### 3.1.4.0 Reservoirs

3.1.4.1 Besides being keystones of development, reservoirs formed due to damming of rivers are a veritable source of fish production. They have requisite ingredients for fishers, anglers, bird watchers, tourists and naturalists etc. Presently, the area under reservoirs is 3.15 m ha. It is expected to reach 4.0 m ha by the end of the next decade. At present level of utilization, they yield on an average 20 kg/ha, which hardly matches with their potential.
Box-2

Reservoir Fisheries (Gobindsagar, Himachal Pradesh) – a successful story

Gobindsagar reservoir is located in Bilaspur district of Himachal Pradesh. The reservoir is formed on the river Sutlej and covers an area of about 10,000 ha at effective storage level. The water spread at full storage level encompasses 16,000 ha. Gobindsagar is one of the best-managed reservoirs in the country from the fisheries point of view. The average fish production from the reservoir during the last five years was about 1,000 tonnes per annum or 100 kg/ha/yr. The maximum yield obtained from Gobindsagar has been to the tune of 122 kg/ha/yr, which is the highest in the country for a large reservoir.

The reservoir has a predominant fauna of the exotic Silver carp (about 60–65% of the total catch) followed by Indian major carps (20–25%), Mahseer species (8-10%) and Minor carps (8 – 10%). The Indian major carps are dominated by *Catla catla*. The Department of Fisheries, Government of Himachal Pradesh implements several welfare and production oriented schemes for the benefit of the reservoir fishermen. These Centrally Sponsored Schemes include, Saving-cum-Relief Scheme, Group Insurance Scheme for Active Fishermen and the Housing Scheme. The Schemes implemented under the State Plan include Risk Fund Scheme and a Calamity Relief Scheme.

Besides closed season, which is implemented in the reservoir for 2 months (1st June through 31st July) every year, areas suitable for natural breeding in the reservoir are also protected to allow the fishes to breed and thereby help in auto stocking of the reservoir. To maintain species balance, supplementary stocking is done from time to time.

About 3000 registered fishermen inhabit the periphery of the reservoir of which about 1900 are active. These fishermen are grouped into 16 co-operative societies, which are then grouped into an apex body called the Bilaspur Fisheries Marketing and Supply Federation. The Federation assists the fishermen in sale and marketing of fish (including retail marketing, if necessary) and its assets include a cold storage, an ice plant and refrigerated vans. The Gobindsagar fish is marketed in major towns/cities in Punjab, Jammu and Kashmir and Delhi and also the bordering areas in Uttar Pradesh and Haryana.

Gobindsagar is an excellent example of a well-managed large reservoir and the practices adopted need to be replicated in other large and medium reservoirs of the country.

Management of a reservoir is in fact governance of a water body, which includes a variety of issues ranging from property rights, involvement of stakeholders, strict regulation, good research and appropriate choice of policy. A three-pronged strategy comprising selection of appropriate mesh size, increased stocking support and fishing efforts can however substantially catapult the fish catches of reservoirs. In case of small reservoirs, stocking alone could be more effective in improving the yield as success in the management of small reservoirs depends solely on recapturing the stocked fish. The main management principles suggested in the management of small reservoirs are: i) determination of ideal stocking density derived on the basis of hydro-biological
parameters; ii) selection of right species derived on the basis of fish food resources and iii) proper stocking and harvesting schedule.

3.1.4.2 The fisheries potential of large reservoirs is largely under utilized as evidenced by low production, low income and poor inventory building exercises. The management policy in large reservoir needs to have twin objectives of development and conservation. Further, the poor marketing infrastructure has also depleted the incentive and returns of the fishermen. There is a need to evolve a package approach comprising stocking, monitoring, equitable and just royalty arrangements, market intervention through cooperatives/corporations and quick transport/distribution channels etc. Fisheries Department must be consulted by the Irrigation Departments of States while managing the water resources, since single-minded attention to irrigation can work to the serious detriment of the fisheries resources. Water allocation policies should be in tune with the biological threshold levels for fisheries so that both the water resources and fish resources could be optimally utilized. In fact even while the Irrigation Department could continue to manage the headworks and the canals, the management of the water resource for fisheries in terms of stocking, exploitation, conservation, fishing rights etc., must be under the exclusive control of State Fisheries Department, if the production and productivity of fisheries in reservoirs is to be raised.

3.1.4.3 Indian reservoirs are distributed under divergent geoclimatic and environmental conditions and classified as small (< 1000 ha), medium (1000-5000 ha) and large (> 5000 ha). Fish catches from these reservoirs is exceedingly low - an average 12 kg/ha in case of large and medium and 50 kg/ha from small reservoirs; Notwithstanding the low levels of yields, there are a few reservoirs in the country where good management practices have resulted in increased catches, comparable to the world’s best reservoirs. Gobindsagar (H.P.) is one such example where management/scientific intervention has yielded positive results and an annual production level of 120 kg/ha has been achieved. Poor management and inadequate stocking are the main reasons for low fish production. It is recommended that:

a) All small reservoirs comprising 98 % of the total reservoirs of the country be developed as pure culture fisheries units;
b) Medium and small reservoirs be developed by proper conservation, added stocking efforts and involvement of fishermen.

3.1.4.4 Some other measures for raising fish production from manmade impoundments are strict enforcement of management rules, observance of close season, provide training and fishing tools to fishers and last but not least, observing ethics of responsible fisheries.

The recommended stocking rates for different types of reservoirs are:

**Table 3: Stocking rate and expected fish production of different sizes of reservoirs base**

</tbody>
</table>

3.1.4.5 The cumulative fish seed requirement for the development of fisheries in exploited reservoirs would be around 350 million fingerlings and the country’s hatcheries are very well in position to meet this demand. The stocking of the reservoirs will have to be continued regularly for a period ranging from 5-10 years. The present system of auctioning and leasing is highly detrimental on long term basis and needs to be replaced by cooperative, SHG system; management of reservoirs by fishermen cooperatives needs to be promoted in order to increase the efficiency and production levels; since fishermen have been proved the best managers, involvement of fishermen residing around the reservoirs is highly important. Observance of close season, mesh size regulation are highly important in conserving the stock. Besides training, Fishermen’ Welfare Schemes such as providing subsidized fishing nets/boats/tents, close-season assistance, premium free insurance, calamity assistance and establishment of fisheries villages need strengthening in terms of level of benefits. In fact, atleast Rs. 1500 per month for the non-fishing months should be available instead of the present level of Rs. 300 per month, in view of the increased costs of living. An additional allocation of Rs. 50 crores per annum adding to Rs. 350 crores upto the end of the 11th Plan should be provided for this purpose from the Government of India.
3.1.4.6 With the launching of ICAR funded All India Co-ordinated Research Projects on five large reservoirs located in different agro climatic regions of the country, considerable baseline information on the limnology and fishery of major reservoirs has been generated and management norms evolved. Under these norms, following select management measures on large, medium and small reservoirs could yield production levels of 100, 75 and 50 kg/ha respectively. Taking these production levels into consideration the country’s reservoir fish production could be raised from 94,000 tonnes to 2,45,000 tonnes, constituting an increase of 160%.

### Development of fisheries in flood plains/ wetlands

3.1.5.1 Freshwater wetlands are extensively spread particularly in Assam, U.P., Bihar and West Bengal and estimated to cover 20 million ha of water in the country. The wetlands are ecosystems where water and land meet. In view of their nutrient status, largely due to predominance of aquatic plants (including weeds), fish production from these water bodies ranges from 100-150 kg/ha, though in view of their organically rich characteristics they have the potential of yielding 1000 kg/ha. The general strategy for development of these wetlands should be to clear them from weed infestation and undertake stocking of fingerlings of grass carp, common carp, *L. rohita* and *C. carpio. and C. batrachus* in the ratio of 10:10:20:30:30. National Rural Employment Guarantee Programme or Food for Work Programme should be used for clearance of weed infestation and the weed could also function as green manure.
3.1.6.0 Estuaries / Coastal waters

3.1.6.1 Estuaries or coastal waters of the country having potential for brackish water fish farming are of the order of 1.23 m ha. These are the most productive estuaries system in the world with average yield varying from 45-75 kg/ha. Out of the total area, 80% is under traditional farming system and the remaining is under extensive or semi-extensive shrimp farming. The activities of shrimp farming on commercial scale have been taken up in the States of Andhra Pradesh and Tamil Nadu while traditional farming is practised in West Bengal and Kerala.

3.1.6.2 The flood plains of Ganga and Brahmaputra rivers have the distinction of nurturing some of the finest wetlands of the country which perform a variety of social functions. These natural ecosystems have intimate relationship with mankind since their inception both directly (fishery, irrigation, industry, recreation) as well as indirectly (recharging of ground water, climate regulation, soil protection, aesthetic values etc.). An estimated 2.0 m.ha of flood plain lakes is available in the country where fish and fisheries remains a traditional economic activity with tremendous socio-economic impact on the rural sector.

3.1.7.0 Cold Water Fisheries

3.1.7.1 The cold water fisheries resources comprise high and mid altitude lakes, rivers, streams, tributaries and reservoirs fed by such rivers. These resources are poorly developed primarily due to lack of scientific and development efforts. The waters maintain fairly low temperature, which obviously support scanty primary and secondary productivity leading to slow growth of fishes. However, while cold water fisheries constitute a small part of the total fish economy, its importance in the larger context of the environmental quality of the river system should not be underestimated.

3.1.7.2 The common cultivable species in the hill States are Mahseer (T. spp., A hexagonolepis), Snow trout (Schizothorax spp.), Mirror carp (C. specularis) and the introduced trouts (Brown and Rainbow trout). In view of its prolific breeding propensity, hardy nature, quick growth and consumer’s preference, mirror carp is the most common fish in stagnant waters. However, due to repeated inbreeding, the species has of late been showing syndromes of genetic fatigue reflected in the form of poor health and slow growth as well as low survival rates. Among the indigenous species, snow trout
(Schizothorax) is the most important in rivers and streams but its stock is declining. Mahseer is a highly important fish of the cold water both as a commercial and sport fish. Though successful attempts have been made for the breeding and seed raising of mahseer, large scale seed availability of seed of golden mahseer (T. putitora) is still a constraint.

3.1.7.3 The most important aspect of cold water fisheries is that they provide excellent sport. Trout and mahseer are world known game fishes providing ecstatic pleasures to anglers. Kashmir, Himachal Pradesh, Uttarakhand, North Bengal, Nilgiri, Kodai hills and Munnar High range offer excellent game fishery to anglers. The approximate resources of cold water States in India is given in the table:

3.1.7.4 Successful rainbow trout farming has been achieved in J & K and H.P. Private farming units in the form of battery of raceways have also been set up in HP and the trout production from these two States alone has gone up to 150t/yr annually. It is important to consolidate success both in strength and scale. The issues being confronted in further
boosting the production are marketing, largescale availability of trout feed, crop insurance etc. and require early solution. The Country’s cold water States have the potential of producing a minimum of 2000 tonnes of trout within a short spell of time. Stock of brown trout (*Salmo trutta fario*) – anglers’ favourite, is fast declining both from the farms and streams of cold water States underlying an imperative need to build up the stock of this world famous sport fish either by importing the new strains or intensification of efforts in our farms.

3.1.7.5 The cold water rivers/streams are under growing pressure. In addition to the degradation of water quality, a more serious problem is the disruption of flow pattern with impact on the quality of waters. Besides obstruction of migratory path of major cold water fishes like trout and mahseer, dam construction or channelisation or diversion of water are instrumental in vitiating the natural biological production cycle.

### 3.1.8.0 Future Challenges

3.1.8.1 The future challenge for open-water fishery is very demanding. Not only have we to make efforts to sustain the existing contribution to inland production basket but also find ways and means to raise this productivity. This has to be achieved in spite of deterioration of open-waters in quality and likely reduction in quantity as well as ever increasing demand for other sectors. Water is critical for fish; it has non-consumptive use in fishery sector. It also acts as substrate for its growth and sustenance. Therefore, any water management issue affects fishery directly. The emerging freshwater scarcity needs to be recognized as an issue of utmost importance. There is a growing awareness that increased water use by humans not only reduces the amount of water available for future industrial and agricultural development but also has a profound effect on aquatic ecosystems and their dependent aquatic life including fishes. Balancing the needs of the aquatic environment and other uses is becoming critical in many of the river systems in the country as population and associated water demands increase. In this context, what is often lacking is the understanding that planning environmental water allocation means striking the right balance between allocations of water for direct human use and indirect human use.
3.1.8.2 A recent assessment of the status of freshwater ecosystems showed that their capacity to provide the full range of such goods and services appears to be drastically degraded. Many freshwater species are facing rapid population decline or are threatened, and yields from many open-water fishery resources have dwindled as a result of interrupted water flow, habitat degradation and pollution. In order to sustain the ability of freshwater dependent ecosystems to support food production and biodiversity, environmental flows especially of rivers and streams must be established scientifically, made legitimate and maintained.

3.1.9.0 Culture fisheries

3.1.9.1 Aquaculture accounts for 70% of the total inland fish production of the country. Besides the exploitation of traditional resource of ponds/tanks, the available technologies have made it possible to utilize small reservoirs and canals too for aquaculture. As per rough estimate only 65% of the pond culture resources had been brought under fish culture mainly through FFDA with average yield of 2,200 kg/ha by 2001-02. There is thus considerable scope for enlarging the coverage and bringing the remaining ponds/tanks/small reservoirs under fish farming.

3.1.9.2 Aquaculture has shown continuous expansion since 1980 and has maintained its position as one of the fastest growing food production activities in the country. The average growth rate of 12.4 % during 1990-96 verily shows the potential of the sector. Aquaculture has been recognized as a major economic activity among the agrarian population and is gaining popularity especially among the rural unemployed youths.

3.1.9.3 The freshwater culture resources in the country comprise 2.25 million ha of ponds and tanks; 1.3 million ha of beels and wetlands; 2.09 million ha of lakes and reservoirs, 0.12 million km of irrigation canals and channels and even paddy fields.
Table 6: Fresh water aquaculture at a Glance:

| 1. Water area available under pond/tanks | 23,58,634 ha |
| 2. Present Annual fish production       | 22,42,170 t  |
| 3. Fish production aquaculture          | 15,12,000 t  |
| 4. Area still to be brought under fish culture | 11,99,500 ha |
| 5. Projected cumulative fish production  | 33,12,800 t  |
| 6. Mean projected unit area production  | 2.672 kg/ha/yr. |
| 7. Requirement of fry                   | 15362 m      |
| 8. Requirement of feed                  | 52,04,500 t  |

3.1.9.4 India is basically a carp country with 84% of our fresh water production being contributed by carps alone. Research investigations undertaken in the country’s fisheries institutions resulted in the development of over two dozen high yielding technologies including composite fish culture involving combination of indigenous (C. catla, L. rohita and C. mirgala) and exotic carps (H. molitrix, C. idella and C. carpio). By extension of this technology through FFDA, it would be possible to boost the aquaculture programme. Later a few other eco-friendly technologies based on utilization of farm’s wastes and other byproducts that do away with the cost on feed and fertilization, can be passed on as alternate choices to farmers.

3.1.9.5 The possibilities of integration of fisheries with agriculture and livestock viz. paddy, pigs, poultry and ducks, have opened new possibilities for enhanced income and more ecologically suitable practices. Cattle dung when used as a fertilizer ensures fish production rate of 3-6 t/ha. Use of biogas slurry and aquatic weeds has also been tried successfully. The excreta of pigs, poultry and ducks form valuable feed, especially for organic fish farming. The fish in turn feed the ducks. Similarly, large areas growing paddy can support fisheries, which in turn add to the paddy yield. Extension machinery in agriculture should more actively encourage the adoption of these practices for which the technologies are available in the country. China in particular has benefited substantially from these practices.
Box - 3

Success of Carp Farming in Andhra Pradesh, Haryana and Punjab

Andhra Pradesh, Haryana and Punjab have emerged as the most progressive States with respect to the development of freshwater fish farming in the country. While Andhra Pradesh was to some extent a traditional fish farming State, Haryana and Punjab are non-traditional States and fish farming started only during the early seventies. Today, fresh water fish from Andhra Pradesh is marketed in about a dozen other States (all the States in the NE region, West Bengal, Orissa, Bihar and eastern Uttar Pradesh) and also in the neighbouring countries - Bhutan and Nepal. Similarly, fish produced in Punjab and Haryana is marketed in the neighbouring States after meeting their own requirements.

In Andhra Pradesh, the Kolleru Lake area is the hub of freshwater fish farming. Besides, Indian major carps (IMC) such as catla and rohu, farmers also raise catfishes like African magur (Clarias gariepinus) and Pangasius sutchi. The average productivity from the farms in Kolleru Lake area is around 5-6 tonnes per ha and scientific methods of farming are deployed to maximise the returns from the ponds. The seed and feed inputs are well organised in the area, which is a big support to the fish farmers. Similarly, the marketing infrastructure is also well knit that takes care of the fish transportation by refrigerated vans to far-flung areas of the country. Per hectare production in Haryana and Punjab is close to 4000 kg and besides Indian major carps, the farmers are also raising freshwater prawn. In these two States, the markets are close to the production centres and, therefore, the per kilogram realisation to the fish farmer is much higher as compared to what the farmers get in Andhra Pradesh.

Freshwater carp farming in the above-referred States exemplifies the innovations and ingenuities of the small-scale fish farmer in optimising per hectare yield from the fishponds and are worth replication in the other carp farming areas of the country.

3.1.9.6 Air breathing catfish culture (C. batrachus and H. fossilis) known for their medicinal properties are in great demand. Though hatchery technologies for their seed production have been developed, large-scale seed availability is still a far cry. Presently, the seed is collected from the wild for stocking the ponds. The culture of these fishes is highly suitable in shallow, seasonal and weed-choked ponds along with trapa (Trapa. bisponsa) and makhana (Eurale. ferox) as practised in north Bihar and eastern Madhya Pradesh.

3.1.10.0 Trout farming: Advancement and scope

3.1.10.1 The farming of rainbow trout (Oncorhynchus mykiss) on a commercial scale has been made possible in the hill States of the country. All impediments pertaining to breeding, farm husbandry, production of high conversion feed have been circumvented and the sole irritant, viz. disease infestation in the farms, has also been taken care of to a large extent by establishment of a national pathological laboratory at Indo-Norwegian Trout farm Patlikuhl. This laboratory is in a position to cater to the need not only of
Himachal Pradesh trout growers but also the farmers of J&K and Uttaranchal as well as other parts of the country. A team of departmental workers has been trained from National Veterinary Institute, Oslo, Norway and these personnel have attained sufficient expertise in tackling trout pathological aspects. Regular surveillance and monitoring is being maintained of the trout stock of all the trout growers of the State. Marketing, being a very important issue, a national level marketing study has been conducted through Tata Consultancy Services (TCS), which incorporates assessments regarding domestic and export potential of the trout. Production levels are being upgraded and a vision plan has been prepared by the State of Himachal Pradesh envisaging a trout production level of 500 tonnes within three to five years. Similar production multiplication programmes have been made by the States of J&K and Uttaranchal. The programme is receiving a big boost with the release of financial packages to hill States (viz. J&K, HP, Uttaranchal and Sikkim) by Government of India for construction of hatcheries, establishing feed mill, liberal subsidy to trout growers, inventory survey of fisheries resources, habitat restoration etc.

3.1.10.2 All the country’s hill States now have modern trout hatcheries, battery of raceways, feed mill plants and other farm infrastructure. The development in trout fisheries has generated tremendous enthusiasm among the local hill inhabitants in taking up trout farming as full time vocation. A number of trout farming units have already been set up in the state of Himachal Pradesh, Uttaranchal and Sikkim and are adding to the income and prosperity of growers.
Successful Trout Farming in private sector in the state of Himachal Pradesh/J&K

The successful implementation of two foreign aided projects (supported by EEC and NORAD) in the field of rainbow trout farming in the States of Jammu and Kashmir and Himachal Pradesh have brought new hopes and prospects in the development of cold water fisheries resources of the country. The farming of rainbow trout (*Oncorhynchus mykiss*) on commercial scale has been made possible in the hill States of the country. The farming system demonstrated in the State run farms have generated tremendous enthusiasm among the local unemployed youth to take up farming of trout fish as a means of livelihood. With the support, motivation and knowhow by the extension wings of State Government better farming units have come up even in the remote hill pockets of the States of Himachal Pradesh, Uttarakhand and Sikkim.

The main reasons attributed to the up front acceptance of the technology success by the growers are:

i) Import of quick growing European/Swedish strains of rainbow trout.

ii) Modernisation of trout hatcheries vis-à-vis easy and adequate availability of troutlings to private trout growers.

iii) Evolvement of compounded pellitized feed for all the stages of trout with high FCR, appetite value and stability factor.

iv) The bulk quantities of farm-reared trout seed and its transplantation in rivers and streams has contributed significantly in the revival of sport fisheries in the states.

Country’s trout farming programmes need strengthening both in strength and scale. Against the current production of 150 tonnes farm-reared rainbow trout annually the production could be raised ten fold within a short period. The success achieved in the states of Himachal Pradesh and J&K in trout farming is worth emulating by other states for generating employment and raising proteinous food for hill inhabitants.

3.1.10.3 The current production level of trout of 150 tonnes annually can easily be raised manifold among the hill youths. Entrepreneurs are also evincing keen interest in establishing large farms and entering the export market. The only action required is simplification of rules in the acquisition of land for these investors.

3.1.10.4 The high altitude snow bound lakes located all around the mid-Himalayas could be developed as Angler’s paradise. The only requirement is the ranching of fry/fingerlings of game fishes viz. lake trout (*Salvelinus namycush*) and Arctic char (*Salmo Salar*) - all excellent game fishes and stocked world over in high altitude waters.

3.1.11.0 Species diversification

3.1.11.1 As per FAO, India utilizes only three bio-categories and 15 species in contrast to 29 by China, highlighting the need to diversify aquaculture and ensure
sustainability and increase in farm production. The thrust as in diversified production must cover both technological and non-technological aspects such as consumer preference, the economics of production and marketability of the selected species. It is time that the available technologies for nationally and internationally breeding and culture of murrels, minor carps and large catfishes, are utilized by scientific institutions/State departments and industry more comprehensively. Though hatchery seed of mullets, mahseer, snow trout, catfishes air breathing fishes are not available in required quantities, yet considering their high price, these would be welcome addition to the fresh water aquaculture system.

3.1.11.2 Yet another critical infrastructure gap relates to setting up of model large scale hatcheries particularly for targeting the hitherto under-utilised species like trout, mahseer, Sea-bass and Sea-bream, etc. These hatcheries would have to be in the public sector for supplying brooders to recognized private sector hatcheries and to provide seed directly to fishers. It is proposed to set up 10 such hatcheries in different States at a cost of Rs. 1.5 crores per hatchery.

3.1.12.0 **Introduction of new species**

3.1.12.1 There has been a continuous debate on the subject of the introduction of new species in the country. With the setting up of National Committee on Introduction of Exotic species in the country by Govt. of India, a very restrictive view or a blanket ban may not be in the long run interest of the country and introduction proposals must be considered on merit and with a forward looking view. The role played by some of the exotic fishes viz. trouts, silver carp, grass carp, mirror carp in raising country’s overall fish production cannot be overlooked. Many countries in our neighbourhood have benefited from the exploitation of exotic species. The scientific development and
emerging technologies, monosex populations etc., would be able to offset the adverse impacts, if any, of these introductions. It may not be desirable to legalise entry or allow introduction of such species like African carp (*Clarias gariepinus*), which could play havoc with the country’s aquaculture programme in view of its voracious carnivore feeding regime. However, some other species deserve introduction for enrichment of stock and tapping of opportunities which have hitherto remained unexploited.

3.1.12.2 The high attitude lakes dotted all along the foothills of Himalayas, though important potentially for development of sport and food fisheries, are currently lying severely under-utilized. Both rainbow and brown trout have failed to establish themselves in view of extremely low high altitude water temperature during a major part of the year. Suitable species for such arctic, lentic, glacier-laden waters are Arctic Char (*Salmo salar*) and lake trout (*S. fontinalis*). It is recommended that eyed-ova of these species may be imported as establishment of these species in these upland waters would not only provide protein and livelihood to hill inhabitants which have little income opportunities but also promote sport fisheries in these far flung pockets.

3.1.12.3 Another exotic freshwater species on the horizon is *Tilapia niloticus*. Highly popular as a food fish in neighbouring countries, this *easy to breed - quick to grow* fish has high consumer’s performance in international markets although it has its defects too. Some stakeholders felt that it could be useful for India since it could reduce our over-dependence on *P. monodon* for export and also allow participation of fresh water fisheries in the export arena. However, since there is some controversy about its suitability for Indian conditions, its performance in water bodies where it has already been grown, through the backdoor should be studied in a time bound manner by a small group of experts and industry. The Department of Animal Husbandry, Dairying and Fisheries (DAHDF) should set up this group.

3.1.13.0 **Culture of Air breathing fishes**

3.1.13.1 In view of consumer’s preference and medicinal values, the air breathing fishes viz. *Clarias batrachus, Anabas testudineus, Heterophenstes fossilis* command high price in fish markets. These fishes have an advantage of growing in shallow, seasonal, muddy, weed-choked ponds, scattered in the villages of UP, MP, West Bengal, Assam,
Orissa and northeastern states. These fishes are also easy to transport, requiring less water and are quite hardy for long transportation route. Presently, the seed of these fishes is collected from the wild as large-scale seed availability of both Magur and Koi is not there.

3.1.13.2 In Thailand, *Clarias maculates* is being bred by specialized breeding techniques and rearing is done on a large scale. Production rate as high as 30-60 tonnes/hectare have been reported. The Thai Magur also grows 3-4 times more than Indian Magur and attains size of 600-800 grams in one year. Considering the potential of promoting air-breathing fish culture programme in the country, research institutions should go in for large-scale brooder seed production of both Magur and Singhi. Some stakeholders have also felt that Thai Magur (*C. maculatus*) should also be introduced on a large scale. However, there is some controversy about its suitability for Indian conditions and its performance too should be studied by a group consisting of experts and industry to be set up by DAHDF.

3.1.13.3 Similarly, large catfishes, especially *Mystus seenghala* and *Wallago attu*, are in great demand among the consumers in north Indian states. While no technology on breeding and raising large-scale production of these catfishes is available in the country, great strides have been made in America and other European countries on intensive monoculture of Channel catfish (*Ictalurus punctatus*). The import of technology of Channel catfish farming under a bilateral project, would perhaps be a step of great economic importance and also meet country’s consumers’ demand of highly sought after catfishes.

3.1.14.0 Ornamental fish culture

3.1.14.1 World trade in ornamental fishes has touched a record figure of over US$1 billion and is growing @ 10% per year. Despite vast potential, India’s share in export of ornamental fishes is negligible. A large number of ornamental fishes that abound in the country’s freshwaters viz. *Danio rasbora, Trichogaster spp, Gara spp, Botia spp, Carasius auratus* etc. are known world over. Ornamental fish culture has grown as a cottage industry in several Asian countries with substantial employment potential. Besides being a foreign exchange earner, it has a great domestic market. There is a need
to expand the activities both in mini farms and mega units. Several private farms have sprung up in eastern and southern parts of the country. The ornamental fisheries if developed on commercial scale have the potential of creating large-scale employment for the fisherfolk rendered jobless consequent to depletion of fish catches in the rivers and streams in the country.

**Box - 5**

**Ornamental Fish Culture and Trade (Chennai, Tamil Nadu) - a Success Story**

Kolathur village on the outskirts of Chennai is famous for ornamental fish cultivation by small-scale producers. There are about 600 families earning their livelihood through ornamental fish cultivation in Kolathur and on an average each household in the village earns over Rs 5000 per month through ornamental fish farming. About 45 kms from Kolathur, Gummudippoondi village is another hub of ornamental fish production where women SHGs have successfully taken up breeding and raising of ornamental fish to earn their livelihood.

On the commercial front, the ornamental fish trade is a growing business with Chennai and Kolkata turning out to be the major production and export centres. The domestic trade is a mix of medium and small ornamental fish farmers. In Chennai, many farmers grow fish in their backyards and sell the stock to bigger companies, which are engaged in the export business. The State Government undertaking Tamil Nadu Fisheries Development Corporation (TNFDC) joined the field in 2000. It rears popular varieties like goldfish, angelfish, mollies and fighters in its farm near Coimbatore. The ornamentals are sold in the local markets.

The global trade in the ornamental fish is estimated at Rs 5000 crores, of which India has a minuscule Rs 2.0 crore. This is despite the country’s tropical climate, varied freshwater sources, and 8 000 plus-km coastline. However, the growing demand for ornamental fisheries and the growing interest in aquarium may change all this very soon.

Singapore and other South East Asian countries account for 80 per cent of the global trade. The main markets are the US, the UK, Belgium, Italy, Japan, China, Australia and South Africa. According to industry estimates, India’s domestic annual turnover is about Rs 15 crores, but the global market is much bigger. With its tropical climate, India can become a key player. Many Indian species like catfish, dwarf and giant gouramis, and barbs are popular abroad and fetch good prices.

To popularise ornamental fish production and trade, Kolathur is an excellent example to emulate. It provides a good mix of both domestic as well as commercial-scale production, which largely caters to the export market.

3.1.14.2 There is a need to recognize ornamental fisheries as a potential sector under fish farming; impart scientific orientation to the activity by involving geneticists and pathologists in the programme; activating the role of Govt. of India/ICAR / MPEDA in the promotion of ornamental fish culture in the country and training of riverine
fishermen in the culture and breeding of ornamental fishes/ construction of Aquarium and other configuration are some other issues for consideration and implementation.

### 3.1.15.0 Backyard aquaculture

3.1.15.1 With an aim to promote small-scale fish farming in urban areas, the concept of backyard fish culture or kitchen ponds is getting increasingly popular, especially in South East Asian countries. Common carp and air breathing fishes are most suitable under the backyard fisheries. Being omnivore with wide range of feeding regime, any type of trash food/kitchen refuse could be served to these fishes and converted into fish flesh. India also has several other species, which fits the concept of backyard fish culture viz. magur (*Clarias*), grass carp, *Seenghi Heteroprenstes* etc. All these fishes except grass carp have an additional trait of thriving in shallow, muddy waters. A small pond of 50-100 sq meters can easily meet a family’s demand of fish without involving any recurring cost except the one time purchase of fish seed. Depending upon the inclination and interest of the pond owner, these backyard units could also be used for breeding and raising ornamental fishes and contribute to the family’s income. The concept of backyard fish farming is well accepted in the country and is already prevalent in limited scale in the States of West Bengal and Assam. The present need is to expand it into other states of the country through extension and mass awareness programmes. Both scientific institutions and development departments should come out with pre-packed information and ideal size of backyard ponds, species stocking and growth details etc.

### 3.1.16.0 Sewage fed fisheries

3.1.16.1 Biological amelioration of sewage is a viable option to overcome the problem of large-scale generation and accumulation of organically rich sediment/material. In recent years, sewage fish culture after proper treatment is increasingly being used for production of fish. The fish production levels in the system are quite high while cost of fish culture is greatly reduced in the absence of component of feed and its expenditure. A number of sewage fed fish farming units have been set up in the country especially in West Bengal. Sewage fish culture is also ecologically beneficial and can convert such disadvantaged areas into Bio Parks for leisure activities as in
Mudialy (W.B.) States must launch programmes to encourage municipalities and other local bodies to set up aquaculture based sewage treatment units, which would produce fish and treat the sewage in an ecologically friendly manner. It is estimated that one acre of such a treatment pond would be needed for treatment of one million litres per day of sewage.

3.1.16.2 Gambusia (*Gambusia affinis*) has been recommended for mosquito control in stagnant water due to its preference for mosquito larvae. It is a live bearer and is easy to keep and breed. Care should be taken however, as it cannot survive in highly polluted waters and in community tanks or ponds with other fish since it eats up the larvae of other fish and even its own young. They have been used extensively in USA and also in India in clean wells, small tanks with stagnant water etc. However, fathead minnows, which are hardier and less nasty, are also recommended.

**Box - 6**

**Mudialy Fishermen’s Cooperative Society, Kolkata (West Bengal)**

The Society, registered in 1961, obtained 70 ha.of waterlogged wasteland-cum-garbage dump from Calcutta Port Trust and 10 ha. from the State Government. The Society has since engaged in production of fish in the sewage water and has also set up a Nature Park involving growth of an eco-tourism centre and extensive plantations of fodder plants, dust absorbing plants, canopy trees and agri horticultural plants. In the process, the Society has not only been successful in treating 25 million litres of waste water through biological means for pisci-culture, but has also provided various facilities to its members like daily-wage medical and educational assistance, funeral aid, marriage aid and housing advance. The integrated and mutually beneficial nature of these activities has converted a stinking, disadvantaged area into an ecologically friendly expanse of greenery. The Society has successfully cultured Indian major carps as well as many exotic carps and successfully demonstrated the technology for sewage water fisheries. The work of the Society has won it the National Productivity Award twice as well as Indira Priyadarshini Brikshamitra Award, Award for overall performance in Pisci-culture and Award for Overall Excellence from NCDC. The “Mudialy Model” has successfully demonstrated the feasibility of production of fish and establishment of an eco-friendly facility even while utilising industrial wastewater and disadvantaged wetland.

3.1.17.0 Pen Culture

3.1.17.1 Raising fish seed in pens (fabricated enclosures of bamboos and nylon nets) erected around the marginal areas of beels, chaurs, lakes or even reservoirs is gaining wide acceptance among the fish culturists of Bihar, West Bengal, Assam and some other states of the country. This seed raising system helps in utilisation of organic
matter, especially decayed matter and detritus etc., piled up in the shallower areas of these nutrient water bodies.

3.1.17.2 Taking in view the country’s wide constraints of rearing space in fish farms vis-a-vis high cost entailed in construction of new fish farms, pen culture offers great promise and scope in enhancement fish seed production of the country. It is one such system where seed could be grown in plenty up to fingerling stage for meeting the huge seed requirement of large water bodies including reservoirs without incurring extra cost on feeding the fish seed. Special schemes need to be formulated by State and Central Govt. bodies with an aim to encourage pen culture programme in the country.

3.1.18.0 **Brackish water fish culture**

3.1.18.1 Since 1980, development of brackish water fish culture has been one of the most outstanding features of the aquaculture sector in the country. It has brought substantial economic gains to fish farmers.

3.1.18.2 In India an area of about 1.2 million ha has been estimated as amenable for brackish water aquaculture in the coastal areas of the country out of which 0.14 million ha has been brought under farming. The infrastructure facilities established over the years include hatcheries, both in private and public sector, feed mills in private sector and processing units. Over 0.03 million persons are reportedly engaged as direct employees in shrimp farming and double of this number i.e. 0.06 million are employed in ancillary activities.

3.1.18.3 The Ministry of Agriculture has established BFDAs in the coastal states of the country. Under the BFDA an area of about 1000 ha had been developed for shrimp culture by the agency till 1999-2000. There has been a steady increase in cumulative shrimp production over the years and the production level during 1990-91 was 83,000 tonnes. However, the white spot virus disease outbreak during 1995-96 reduced the production. The production subsequently increased and is presently stagnating at the 1995-96 level. Though a traditional activity, shrimp farming has grown as a commercial enterprise not only among small and marginal farmers but also in the corporate sector. This has improved the rural economy, increased employment, living standards of coastal population and has led to foreign exchange earnings. At the same time, due to
unregulated growth and poor farm hygiene, there have been losses and socio economic problems. Brackish water fish culture deserves expansion after taking the entire ecological aspects into considerations.

3.1.18.4 Production of freshwater prawn, popularly known as Scampi (Macrobrachium rosenbergii) in saline waters particularly in inland areas represents yet another opportunity for employment generation and income. Large areas in the country have suffered from the problem of salinity due to excessive irrigation and inappropriate water management. While these soils have been treated with gypsum to control the salinity, which is costly, a more profitable utilisation of such saline soils can be through culture of Scampi. The technology is indigenously available and the States using the saline soils/water for production of scampi should launch special extension efforts and incentives to popularise freshwater prawn farming.
Farmers’ Associations or Aqua clubs (Thanjavur, Bhimavaram)

(a) Thambikottai-Vadakadu Shrimp Farmers Association in Thanjavur district, Tamil Nadu.

In Tamil Nadu, shrimp farmers in Thanjavur district have formed village level associations and organise regular meetings to follow good management practices for achieving eco-friendly and sustainable shrimp farming. One of the best examples of this association is the “Thambikottai-Vadakadu Shrimp Farmers Association”. The members of this Association consult themselves before initiating pond preparation, introducing water in their ponds, selection and stocking of seed, feed management, shrimp health management, prevention of disease, formation of separate channels for draining out waste water, time for harvest of the crop, fixing of price, etc.

The Association members also inspect the shrimp hatcheries located at Chennai and Marakanam areas and collect seed samples for testing in at least three PCR laboratories to ascertain the presence/absence of pathogens. The tested seed is purchased in bulk, which is then divided amongst the members of the Association as per their requirement. If a viral disease affects any farmer’s crop, all precautionary measures are taken to prevent the spread of the disease to the other ponds. The Association also suitably compensates the affected farmer’s loss. The Association takes the responsibility of road laying and providing other infrastructure like drainage canal and street lamps to the villages adjacent to shrimp farm cluster. The Association organises meeting of the members on fortnightly basis and discusses and solves their problems with mutual consent.

(b) Sri Subrahmanyeshwara Aqua Club in West Godavari district, Andhra Pradesh

To promote cooperative approach in management of shrimp farming activities and other common issues that commonly arise in cluster-based shrimp farms, aqua clubs have been set up in Andhra Pradesh. A total of 128 aqua clubs with a membership of 3367 farmers is now existing in the State. However, one of the best initiative of this kind is the Sri Subrahmanyeshwara (SS) Aqua Club in Mogalthur village is West Godavari district of Andhra Pradesh. The SS Aqua Club comprises 58 farmers with 108 ponds spread over 58 ha and the farmers involved are mostly small-scale, practicing improved traditional farming with low investments. Based on the technical inputs provided by the Network of Aquaculture Centres in Asia –Pacific (NACA), Bangkok and the Marine Products Export Development Authority, Kochi, the farm level ‘better management practices’ or the BMPs were demonstrated in the shrimp ponds of the SS Aqua Club with great success.

The above two initiatives by the shrimp farmers in the Tamil Nadu and Andhra Pradesh need to be replicated in the other coastal states also where shrimp is fast developing on commercial-scales.

3.1.18.5 In India, coastal aquaculture is synonymous with farming of tiger shrimp (*Penaeus monodon*). With the availability of hatchery and grow-out technologies, shrimp
farming picked up momentum during the late eighties, which continued until 1996 when the Supreme Court placed restrictions on intensive scales of technologies, which had adverse impact on the ecology and the environment. However, with the setting up of Aquaculture Authority in February 1997 and regulation of farming activities, the practices have gradually became sustainable. With the enactment of the Coastal Aquaculture Bill by the Parliament in May 2005, shrimp farming activities are likely to get a further boost in the near future. Therefore, it is essential that all future developments in shrimp farming are geared towards practices which are sustainable and do not have any adverse impact on the environment. In this regard, the following recommendations are suggested:

3.1.18.6 To make shrimp farming globally competitive and provide a level-playing field to the Indian growers, it is essential that import duties and taxes on feed and feed ingredients should be reduced. Similarly, reductions in power tariff to bring it on par with agriculture will provide great relief to the shrimp farmers. Presently, industrial rates in power tariff are levied on shrimp farming, which places a heavy burden on the farmers with small holdings.

3.1.18.7 Domestic marketing of shrimp and other seafood should be developed to reduce the total dependence on export market. Development of domestic markets would also necessitate extensive publicity and promotion, which should be undertaken at the national level by utilizing the print and electronic media.

3.1.18.8 Domestication of shrimp brood stock should be initiated through a private-public partnership so that the hatcheries get specific pathogen free and ultimately specific pathogen resistant brood stock for supplying quality seed to the shrimp growers in the country. Central agencies like Aquaculture Authority should also initiate seed certification program to enable the farmers to receive quality seed for raising in their farms. This work could be taken up by the NFDB when set up. There should be a registration of all hatcheries in the States and regular inspection of their brood stock and hatching practices. Air freight for transportation of shrimp brood stock and nauplii should be revised to bring it on par with the rates levied for fish seeds.
3.1.18.9 Shrimp farmers face considerable difficulties in terms of pond water quality and animal health management. Many farmers face heavy losses due to want of timely and reliable advice. It is, therefore, suggested that Aquaculture Service Centres should be set up with the active involvement of the farmers in different production areas. These Centres should be equipped with a laboratory, storage facilities for inputs and with communication facilities. The Centres should be run by trained and capable managers who are available to the farmers to provide reliable technical advice, arrange for procurement of quality seed, feed, probiotics, etc. They should also provide information on the market and price fluctuations to the farmers. The centres should be provided with the initial seed money and should subsequently be self-financing.

3.1.18.10 The coastal States should formulate a sound leasing policy to allot Government land to small and medium farmers, entrepreneurs and corporate houses engaged in shrimp farming. The Coastal Zone Management Plans should allocate lands in the coastal areas for shrimp farming and also permit conversion of unproductive agricultural land for aquaculture if adequate precautions are taken to prevent salt water incursion to the neighbouring agriculture land or groundwater sources.

3.1.18.11 The Banks should provide loans to farmers to undertake shrimp aquaculture. Similarly, crop insurance should also be initiated to protect the farmers from the risk of viral and bacterial diseases and natural calamities such as cyclone, tsunami, floods and droughts. Premium should be fixed at reasonable rates, especially for weaker section/ self-help groups.

3.1.18.12 Shrimp farming is presently centered on a single species *i.e.* *P. monodon*. To make the farming practices sustainable, diversification is necessary and new candidate species of shrimp and fin fishes should be encouraged for which technology is either indigenously available or needs to be sourced from other countries. The role of the Government in this regard is paramount and it should catalyse the entry of new candidates into the farming systems.

3.1.18.13 Potential lands for coastal aquaculture have been given on long-term lease to private entrepreneurs for salt production. Such lands in many parts of the country are not being used profitably due to various reasons. The Government should review this lease policy and permit shrimp and fish culture in salt land and salt affected areas.
3.1.18.14 All shrimp farms and shrimp hatcheries should be registered with the Aquaculture Authority. However, the registration process should be simple and easy to comply with. Each registered farmer and hatchery operator should be given an identity card and the period of registration should match the repayment period of bank loan.

3.1.18.15 The coastal States/Union Territories should formulate Integrated Coastal Zone Management Plans, which should include areas suitable for development of shrimp farming. Fresh micro level survey to identify potential land for coastal aquaculture should be conducted to arrive at the correct estimate. Larger areas should only be taken up after environment impact assessment studies are conducted. Permission should be given for water intake through forest land wherever necessary.

3.1.18.16 Considerable communication gaps exist between scientists and farmers. The Fisheries Research Institutes under the ICAR system should provide technical support to the Aquaculture Service Centres on a day-to-day basis and inter-alia assist them in water and soil quality and aquatic animal health management. The concerned ICAR Research Institute should also undertake surveys on wild brood stock of important aquatic species, prioritise research programs on domestication of *P monodon* and establish laboratory facilities to test antibiotic residues at appropriate places.

3.1.18.17 Shrimp farms draw water from the creeks and estuaries, which also receive pollutants from point and non-point sources of pollution. There, it is essential to regularly monitor the pollution levels so that they do not adversely impact the development of shrimp farming. Similarly, the waste water from the shrimp farms needs to be monitored and adequately treated before it is released into the open waters. The use of mangroves, mussels and oysters, seaweeds and sea grasses should be encouraged to reduce the levels of organic matter in the wastewater.

3.1.18.18 Shrimp farming provides livelihood support to about 1.0 million people in the coastal areas, besides making substantial contributions to the foreign exchange earnings of the country. To ensure sustainable growth of shrimp farming in the country, the government should assist in setting up of infrastructure such as common effluents treatment plants for cluster-based farms, domestication of shrimp brood stock, opening of bar mouths and dredging of channels and creeks for flushing at regular intervals.
In view of the importance of shrimp in the fisheries basket especially for exports and its contribution to export earnings and looking to its vast employment potential using the brackish water resources of the country, it is proposed to identify a cluster of shrimp farms and shrimp estates where common infrastructure consisting of intake/settling reservoirs and effluent treatment etc. would be provided in the public sector, even through user charges could be levied on the fishers. It is to be noted that the Government does invest substantially for such common infrastructure for export oriented activities like Export Promotion Industrial Parks, Export Promotion Zones etc. It is proposed to set up 10 such clusters in the relevant States @ Rs. 5 crores per cluster.

**Box - 8**

Success achieved in raising Shrimp and Scampi Seed Production in Chennai/ Pondicherry

Presently, about 237 shrimp hatcheries have been set up in the coastal states with an installed capacity of about 12 billion seed per annum. Of these as many as 110 have been set up in Andhra Pradesh, 67 in Tamil Nadu and 21 in Kerala. In Orissa, 13 shrimp hatcheries exist.

Practically, all hatcheries were set up to breed tiger shrimp, *Penaeus monodon*, with some also breeding *P. indicus*. However, during the last 4-5 years, many of these hatcheries have also started breeding freshwater prawn, *Macrobrachium rosenbergii* (scampi).

Most of the modern and state-of-art hatcheries are located either in Kakinada area in Andhra Pradesh or in the Chennai – Marakanam belt in Tamil Nadu. These hatcheries are an excellent example of the efforts that have gone towards the development of commercial-scale shrimp and scampi farming in the country and any further development envisaged in this sector has to keep in mind the hatchery infrastructure set up so far. It may be noted that scampi production is quite spread unlike shrimp production, which is in clusters. Scampi, which represents a major strength for Indian fisheries, since it can be grown profitably in inland areas even in the North India in slightly saline conditions, is especially amenable to contract farming.

### 3.1.18.20 Economics of Aquaculture

ICAR has estimated the economics of various categories of Aquaculture as under:

1. **Carp polyculture**

<table>

3.1.19.0 Running Water Fish Culture

3.1.19.1 Hills have more water than land. Schemes such as running water fish culture offer great scope and promise in the expansion of aquaculture in cold water states. The system is highly remunerative as richly oxygenated water - the critical component is available in abundance in hills enabling the culturist to undertake 5-10 times stocking densities. A crude type of running water fish culture system (RFS) called Johra fishery is being practised in the hilly pockets of Tripura and West Bengal. An improvised version is found in Himachal Pradesh. The RFS system is totally feed based and the cultured fish species are common carp and silver carp. Production rates as high as 54 tonnes/ha. have been reported by the Central Institute of Fresh Water Aquaculture (CIFA), Bhubaneswar. There is a need to enlarge the number of fish species for culture under RFS and standardize rearing protocols.
3.1.20.0 Quality control in seed

3.1.20.1 With the evolvement of technology of induced breeding by the ICAR institutes in the country and its later transference to State departments and various entrepreneurs, a large number of hatcheries have been set up in both private and public sector in different parts of the country. As per information, as of today, there are 911 carp hatcheries in the country. The nursery area available in government fish farms is around 2,893 hectares. In terms of fry, the production currently is around 18,500 million, with West Bengal, alone producing over 50% of the country’s total seed production followed by Assam. In the uplands, there are 23 rainbow trout hatcheries, in the States of Himachal Pradesh, J&K and Uttaranchal.

3.1.20.2 The mushrooming of seed production hatcheries has given a much needed thrust to the fish/prawn farming programme in the country but on the other hand, it has promoted sale of substandard and suspect quality seed. There is now a need for establishment of a **National Agency and Protocol of Seed Certification** in the country. A solution lies in the registration of all hatcheries by the State departments, followed by regular inspections of the brood stock and seed produced by a team of officers with representatives of research institution/SAUs and State fisheries department. The parameters for examination may include health status of brooders, hygienic standard of farms and condition of produced seed. Based on the inspection, the hatcheries may be approved for supply of seed to farmers and issuance of Accreditation Certificate. Further, each seed consignment packed for sale may be labelled indicating quality, quantity, batch number of species of fish and other relevant details. The state Accreditation Committee may keep surveillance and periodically check the hatcheries stocks. The seed supply would invariably carry stamp of the hatchery on the consignment meant for transportation. In case of any breach of rules by the hatchery operators, the accreditation committee would have the right to blacklist the firm and even cancel the registration of the firm. Such a measure is necessary for ensuring production of quality seed in the country and put a check on sale of substandard and dubious quality seed. The action is vital to protect the genuine seed suppliers and lend credibility to fish seed trade in the country.
3.1.20.3 Even while the ICAR system has an array of specific institutions concentrating on various segments in the fisheries sector, their contribution can be further enhanced if they move strongly into domestication of globally available technologies, consultancy to fishers and corporate sector, large scale production of brooders for recognized private sector seed producers, sale of good quality seed, especially for hitherto under-utilized species etc. These institutions could be encouraged to link their outlays to outcomes for meeting the felt needs of the fishers and to prepare a bankable project in this regard through Special Purpose Vehicles (SPVs) for undertaking commercially viable activities for production of brooders/seeds/other items of use for fishers. They could be provided margin money assistance of Rs. 30 crores for attracting institutional finance.

3.1.21.0 Quality control in feed

3.1.21.1 Nutritious feed and oxygenated water are key to good health of fish. The nutritional requirement of warm and cold water fishes ensuring high conversion ratio are well known. Formulated feed of carps and fresh water prawn with locally available ingredients have been prepared and marketed by CIFA. Use of probiotics and supplementation with vitamin A and vitamin E has also been worked out for preparing cheap diets.

3.1.21.2 While low quality unstandardized feed is available in the market, certified high quality feed at reasonable rates is still not available. There is a great demand for duly certified fish feed for carps, catfishes, trout and fresh water prawns. The problem is more acute in case of fishmeal, a major feed constituent for raising carnivore fishes viz. trout, mahseer catfishes and murrels. Fishmeal interspersed with sand, prawn meal, rotten blood meal, urea etc. when used as a feed ingredient creates hosts of problem ranging from poor growth to manifestation of diseases.

3.1.21.3 The country’s research institutes have to take a lead in solving this problem. Again, an accreditation cell needs to be set up under an appropriate authority to check and inspect the formulated feed on the basis of proximate analysis, stability ratio, appetite value and above all, Feed Conversion Ratio and subsequent issuance of accreditation certificate to feed manufactures. This would ensure availability of quality
feed to the fish growers and build their confidence on the purchased product and boost profitability of operations.

3.1.21.4 Feed production farms both for fresh water fish and shrimp should be in small size units located near the consumer and aqua estates and suitably dispersed, in order to generate small-scale employment and reduce costs since local material could be used more efficiently.

3.1.22.0 Bio-security from diseases

3.1.22.1 Quite often, a number of diseases are posing a potential threat to aquaculture as well as to wild stock of aquatic life. The emergence of such diseases in countries known to be free from such diseases or even in countries with established control system and eradication programme often result in significant losses. The recent disease epidemic of UDS (Ulcerative Disease Syndrome) or white spot or viral infection *irrido virus* in trout took a heavy toll of fatalities in fish farms. Disease monitoring system in the country is decidedly very weak with disease investigation centers located only in few national fisheries institutes. In view of poor sanitation of farms and non-observance of standard hygienic norms the hatcheries in majority of farms usually become hotbed of disease resulting in poor survival rate and slow growth.

3.1.22.2 Fish health, farm’s hygiene, surveillance of bio-stock are crucial to raise productivity in seed or fish producing centers as well as ensuring bio-security to the stock. Risk factors often posed by the disease in carps, trout and shrimp could be minimized by establishing pathological laboratories equipped with trained staff. Regular surveillance and requisite help to the stakeholders could be provided through these fish pathological laboratories. The need is for the fish grower to accord due priority to fish health and condition of farm’s. Further, we must set up the necessary legal provisions for the implementation of contingency plans. Such legal powers must include provisions for declaring a list of serious diseases for which action is needed, reporting measures for abetting or controlling these diseases and other legal provisions. A list of the crises centers/laboratory information, which has the necessary facilities to control or treat the diseases, should be made widely known to the stakeholders.
3.1.23.0 Organic Fish Farming

3.1.23.1 Based on the principles of protecting the environment, minimising soil and water degradation and optimising biological diversity as well as consumer demand, the concept of organic fish farming has a lot of potential. The system calls for intensive monitoring of environmental impact namely: i) integration of natural plant communities in farm management ii) processing according to organic principles iii) natural breeding protocols iv) use of certified feed and fertilizers v) non use of medicine and synthetic pesticides etc. Demand for organic aquaculture products viz trout, carp and mussel is increasing each year in international markets. There is a tremendous scope in the country to step up organic fish farming in order to fetch better price and profits as well as promote pollution-free fish culture practices. There is a growing awareness about the health hazards that may result due to the consumption of fish grown in polluted environments. DAHDF should set up a small technical group consisting of ICAR, industry representatives and small fisher organizations to work out protocols for organic fish farming which should be feasible, affordable and acceptable to international buyers.

3.1.24.0 Post- harvest Fisheries

3.1.24.0.1 The post-harvest fisheries consist of different type of functionaries working at different levels. The important stakeholders in the post-harvest sector along with their respective roles are as under:
Table 8: Stakeholder groups in Indian post-harvest fisheries

<table>
<thead>
<tr>
<th>Player</th>
<th>Role</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fishermen’s assistants</td>
<td>Mainly the wives of the fishermen are involved in helping the fishers in collecting the catches from the nets for sale after landing. No payment is involved.</td>
</tr>
<tr>
<td>Head loaders</td>
<td>Carry fish from the landing centers to the auctioning site, from auction site to godowns or transport systems. Some of them come from non-fishing communities.</td>
</tr>
<tr>
<td>Poor people collecting fish</td>
<td>Extremely poor people, collect fish from fishers either for free or in a barter system involving sweetmeats, etc. and either sell the fish for money or use for domestic consumption.</td>
</tr>
<tr>
<td>Money lenders</td>
<td>Lend money for business and personal purposes to the fishers and traders. Some moneylenders are involved only in money-lending activities, while others are involved in fish trade also.</td>
</tr>
<tr>
<td>Auctioneers</td>
<td>Auction catches which are landed. In traditional fish landing centers, in places like Chennai, it is exclusively women who act as auctioneers; in some others, it is only men. Some auctioneers are also moneylenders.</td>
</tr>
<tr>
<td>Boat owners</td>
<td>Own different size boats, possibly driver-cum-owner. Operat major mechanized centers.</td>
</tr>
<tr>
<td>Companies/Exporters</td>
<td>Buyers of fresh fish from the port/landing center for export or sale within the country &gt; 100km.</td>
</tr>
<tr>
<td>Agents</td>
<td>Act on behalf of buyers of fresh/dry fish. Accumulate economic lots to be sent elsewhere. Some agents buy in bulk and retail to cycle/moped traders on credit.</td>
</tr>
<tr>
<td>Tricycle and auto rickshaw owners and operators</td>
<td>Hired by the fishers for transporting fish to the wholesale and retail markets.</td>
</tr>
<tr>
<td>Cycle/moped traders</td>
<td>Buy from the landing center and sell in markets in and around the site (upto 50 km); Generally not from the fishing caste.</td>
</tr>
<tr>
<td>Petty traders (head load)</td>
<td>Buy and sell fish (fresh and dry) within 30 km of the site, mostly women, the fishing caste.</td>
</tr>
<tr>
<td>Fish collectors</td>
<td>Appointed by the commission agents, they are paid employees for taking care of collection, storage and transport of the catches from the village too difficult for the agent to access on a regular basis. Could be men or women, almost all of them from non-fishing communities.</td>
</tr>
</tbody>
</table>
3.1.24.1 Fish processing

3.1.24.1.1 Short or long term processing of fish to retain its desired quality is necessary to prevent wastage through spoilage of a valuable product. Domestic markets in India require mainly fresh fish. Indian processors of frozen fish have generally used different types of indigenously fabricated air blast freezers or horizontal blast freezers, some of which are imported while others are fabricated domestically.

3.1.24.1.2 Cold chain concept calls for provisions of integrated facilities to retain the quality of refrigerated or frozen fish from the term of harvesting till it reaches the consumers. The cold chain system requires following facilities:
   a) Adequate supply of ice for holding fresh fish before processing
   b) Containers for holding fresh fish in ice, cold storage at landing centers
   c) Intermediate points on the transit route
   d) Processing, marketing and distribution centers
   e) Facilities at retail markets.

3.1.24.2 Ice plants and production

3.1.24.2.1 There is no authentic study available on the requirement of ice meeting the need of inland fisheries. Ice often has to be transported, over long distance to the landings centers/villages and ponds at considerable cost. The availability of the ice to the producer especially during non-summer months becomes a serious concern. The ice producers, in view of their important role in helping fisheries industry deserve incentive and support. Some of the issues retarding the growth of this important item of infrastructure are constant increase in power tariff on ice plant factories; differential charges on ice plant factories vis-à-vis cold storage; hefty security deposit on quarterly basis charged by the Electricity Department; refusal of banks to advance loan to ice plant factories on viability grounds; high surcharge rate on ice plants even though it is a risk industry. These issues need to be given sympathetic consideration by State Governments since fisheries benefit the poor fishers and the sector can and does contribute to the State revenues.

3.1.24.2.2 Basket made of split bamboos with suitable lining inside are mainly used as containers for fish transportation in the country. Such baskets cause bruise on the fish skin because of rubbing against the rough and tough surface of the baskets. Other types of
containers such as tea chests, old plywood boxes are also used. Cheap containers with proper insulation have been developed but have lacked acceptance. It is important to develop/fabricate better plastic containers at affordable prices.

3.1.24.2.3 The inland sector, although characterized by highly displaced landings, has an advantage in having production sites close to the consumption centers. However, the reservoir fisheries are an exception to this and necessitate strengthening of infrastructure. There is a growing realization that closer ties between primary producers and manufactures would be mutually rewarding, the former being assured of a ready market for his produce at a reasonable price and the later being assured of an uninterrupted supply of raw market for his production line.

3.1.24.2.4 Aiming to create facilities for ensuring remunerative price to fishers and to make available fresh fish to consumers, avoiding slew of intermediaries, the Ministry of Agriculture launched a centrally sponsored scheme with 100% assistance viz. ‘Strengthening of infrastructure for inland fish production in the country’ during 1992-93. Under the scheme, 33 units were sanctioned to 18 States envisaging assistance of Rs. 200 million for creating infrastructure facilities in the form of fish handling sheds, ice plants, cold storage, retail outlets, insulated vans etc. During 2004-05, Ministry of Agriculture sanctioned another scheme viz. ‘Strengthening of post-harvesting infrastructure’ with an objective to reinforce post-harvesting network. The goals laid down under the scheme include developing fish preservation and storage infrastructure; developing marketing network such as retail vending, kiosk, aqua shops, insulated/ refrigerated vehicles, mini trucks, auto-rickshaw with ice box, moped bicycle/bicycle with ice box, fish display cabinets; weighing scales, computer units and allied components. The scheme is being implemented through self-help groups of fisher women, NGOs, cooperatives, joint ventures, Govt. undertaking, co-operatives in a location specific manner. The Government of India, Ministry of Food Processing Industries has also a number of subsidy-oriented schemes for NGOs/ cooperatives, private sector, joint venture etc. The schemes have been designed to provide incentive for setting up value addition projects on fisheries. Subsidy up to 75% is envisaged for providing beneficiaries for setting up unit in remote areas while 50% for other for projects involving cost up to Rs. 10 lakhs. The
assistance is provided ranging from Rs.40-100 lakhs to different categories from private sector to Govt. undertaking.

3.1.24.3 Economics of Inland Fish Trade

3.1.24.3.1 Select families in each market, both at wholesale and retail levels control inland fish marketing as a business. The margin of profit is generally kept high to cover the risk factors. The operation of inland fish is normally restricted in the districts, the inter-districts or inter-state movement is only during the high catch or glut seasons. The price spread and cost of marketing are quite high. The retail price of locally sold fish doubles when compared to the price received by the fisher. The cost of transport, ice, packing, handing, losses and other fixed costs together at wholesaling and retailing hardly ranges 8-12/- kg. Thus there is wide scope of reducing the price spread and increasing the producer share in the consumer rupee.

3.1.24.4 Marketing

3.1.24.4.1 Fish being highly perishable and difficult to handle, the streamlining of fish marketing requires much greater attention and effort. As a first step, the fish collection/auction and distribution centres should be separate from the retailing centres. Hygiene and cleanliness are important in the fish markets. There should be slit-wooden/plastic platforms and plastic sheets for stacking the saleable fish, preferably with provision of water nozzles for maintaining humidity, especially in bulk markets. Movement of fish stacks especially in large auction markets should be in plastic containers in order to avoid damage in crude baskets/bags.

3.1.24.4.2 Fish marketing involves functions from catching of fish to reaching the consumer. Post-harvest fisheries activities including processing, production, development, transport and marketing provide greater employment to labour than the harvesting sector. It is generally felt that post-harvest infrastructure is grossly inadequate in fisheries sector. The retail markets are unhygienic and lack basic facilities. Mostly the whole fish is sold in the market and there is negligible processing/ value addition in fresh water fish marketing. Further the marketing, transportation and storage being handled by
the private sector lack hygiene as well as price norms. This core activity has witnessed a slow growth, lagging far behind the production trends.

3.1.24.4.3 Physical infrastructure for marketing is important. It is proposed to provide composite fish marketing support to the States by setting up 20 units spread over various States for a period of seven years culminating in the end of the Eleventh Plan. The support would consist of assembly and auction market yards, small cold chains through cold storages, refrigerated and insulated vans and mobile retailing. The States could be permitted to have a suitable mix of these elements depending on local requirements. It is estimated that a sum of Rs.1 crore per unit would be needed.

3.1.24.4.4 Mandi/marketing Committee must take the responsibilities of renovation of fish marketing with requisite hygienic standards. A proper layout and design for small and large modern state of art fish markets should be developed by Cultural Institute of Fisheries Technology/National Institute of Agricultural Marketing, Jaipur, according to the conditions and needs of different regions of the country. A scheme should be formulated for development of large and medium fish markets, by tapping institutional finance. It should be realized that improper/unscientific handling in marketing centres can substantially lower the price realization, besides proving to be a health hazard. Foreign buyers too are getting increasingly conscious about the hygienic conditions in the landing centres and markets.

3.1.24.4.5 In particular, Kolkata wholesale fish market being the second largest fish market in the world needs a substantial overhaul. The market must be redesigned with proper layout, auction facility, hygienic, handling of fish and efficient drainage commensurate with the varieties and the volume of fish handled here. The layout would have to take into account the multifarious role of this market for assembly, auction, storage, export and even retail sale of fish. The State Government should prepare a bankable plan in consultation with the stakeholders with margin money from the Central Government.

3.1.24.4.6 It is imperative to ensure proper hygiene in large and small consumers market for fish. Municipal Committees must enforce the laws more strictly in the interest of public health.
3.1.24.4.7 It is further recommended that the present status of Fish Farmers Cooperative Federation should be carefully studied and specific steps should be identified and implemented to rejuvenate this important institution on a sustainable basis, in the interest of the fishers.

3.1.25.0 Socio-Economic Status of Fisher Folk

3.1.25.1 An overview of various studies relating to socio-economic aspects of small-scale fishers usually overemphasize on economic and technical factors rather than social parameters. It is said that, to date, fisheries management lacks the human element i.e. missing of social parameters in decision-making processes.

3.1.25.2 During the last fifty years of continuous development programmes, despite introduction of new technologies in fisheries and aquaculture and progressive increase in budget allocations; the status of today’s average fisherfolk in terms of access to the benefits of development has not changed much. In the Ninth Plan, the Union Govt. allocated around Rs. 207 million to fisheries, 400 times more than its allocation in the First five year plan. In the same period, inland fish production witnessed a growth of 12% and stood at 3.2 million tonnes during 2000-01. However, their socio-economic status has not improved in a commensurate manner. The situation is worse in case of riverine fisher folk, with rivers and streams turning into aquatic deserts. An integral part of the civilization and one of the oldest communities, the traditional riverine fishermen have even fallen below the poverty line. Even the Census of India refuses to acknowledge them as a separate community. We do not seem to have a clear category of riverine fisher folk.

3.1.25.3 Though no official figures are available on the number of riverine fishers. Their population is estimated to be around 0.45 million. A large chunk of the 387 communities of the fisherfolk, identified by Anthropological Survey of India are involved in inland fishing. These fishers are dependent on the 191,024 km of rivers, canals, etc.

3.1.25.4 The traditional fisher folk share an intricate relationship with rivers and they cannot afford to play with it. Non-fishing communities, however, go for maximum extraction. One of the factors quoted for destructive/over fishing is the short duration of lease. The leaseholders want to extract as much fish as possible from the rivers with each passing day of the lease period. Another problem is the use of restricted and destructive
fishing gears. While the traditional fisher’s gear are designed to catch legal-sized fishes, the lessees deploy massive, small meshed mahajal, which virtually sweep entire stretches of rivers without even sparing a fingerling or insect larvae. Further, with the dwindling fish population, locals have resorted to devious methods for catching fish. Poisoning, and electrocuting have become rampant and norms are flouted with impunity. The list is endless. If traditional fishers have to survive, they need help from the authorities.

### 3.1.26.0 Welfare of fishers

3.1.26.1 Welfare of the under-privileged poor fisher has always remained the core objective of Central and State assisted schemes initiated during the successive five year plans. These include subsidized supply of fishing tools viz. nets/boats/tents, premium free insurance, model fishermen village scheme, risk fund scheme of providing financial assistance in the events of floods/calamities, close season periodicity.

3.1.26.2 However, due to poor literacy level among fisherfolk, the effect of some of the welfare schemes have failed to percolate down to the targeted fishers. There is a need to undertake investigative studies to assess the impact of these schemes on the economic status of the fisher to generate benchmark data and initiate new schemes or improvise the existing ones. Since fishable waters are common property resource, competition among fishers often leads to conflicts. Fishing villages all along the riparian areas of rivers reflect backwardness and under-development. Exploitation by contractors who hire them, after seeking fishing rights of reservoirs or other water bodies is rampant. The entire system is disorganized and exploitive. Most of the studies on socio-economic profile of traditional fishers present disturbing trends.

3.1.26.3 There is a need for paying special attention on the subject. The first step is to organize them and bring them under cooperatives or self help groups. A complete registration of fisher population, followed by imparting to them training on latest techniques in fisheries viz. pond fish farming, seed production / integrated farming etc., and providing them fishing tools at subsidized rates and demarcation of riverine, and reservoir stretches etc is needed. Fishing nets and country boats are the two main requirements of traditional fisher which need to be made available to fishers at subsidized

104
cost by the Central/State agencies. Basic amenities such as schools, banks, primary health centres, drinking water taps and other infrastructure facilities also require strengthening.

3.1.26.4 The fisherfolk should be provided access to institutional credit at low rates of interest.

3.1.26.5 With an aim to provide one-time financial help to the country’s aged and poor fishers over 60 year age, an Endowment scheme is recommended for implementation jointly by State and Central Governments, through LIC or any other insurance agency like Agriculture Insurance Company. The Central Government, State Government and fisherman in accordance with a reasonable cost-sharing formula could pay the premium on an annual basis. The scheme could operate through Cooperatives/Self Help Groups for better administration. Financial assistance would be provided to select number of fishermen on the basis of seniority of age, membership period and fixed quota of each state.

3.1.26.6 The Government of India as well as National Centre for Agricultural Economics and Policy Research has suggested certain schemes with an aim of uplifting economic status of poor fishers but in view of poor literacy level and sheer ignorance of the community, the benefits of these schemes have failed to percolate sufficiently to the fishers. Gujarat and some other states have got studies conducted which have shown that the marine fishermen have been benefited when organized under the cooperative fold or self help group scheme.

3.1.26.7 Women have traditionally played a crucial role in the production and marketing of fish. The areas like propagation and seed raising of ornamental fishes, seed raising and farming of trout, which are relatively indoor activities, are highly suitable for adoption as a vocation by women.

3.1.26.8 Retailing/ marketing of fish has for long been done by women in different parts of the country. The present day need is to upgrade their skill in fish marketing, sanitary and hygiene standards of sale shops, upkeep and maintenance of fish texture, quality with an ultimate aim of enhancing profitability in profession. The programme ensuring supply of insulated fish boxes, low cost drying rakes, initiated by Bay of Bengal Programme in the country has shown encouraging results and such efforts need
fortification both horizontally and vertically at state and national level by government and NGOs.

3.1.26.9 Although women contribute a large measure in fish marketing, they do not receive adequate share of the fish income or employment opportunities. The poor self-employed women have a triple disadvantage of being poor, self-employed and being women. They face problems related to posture of work (continuous sitting), their work environment (sitting on the road side for sale of fish) and physical endurance (loading fish containers on her head), besides the repetitive nature of movement from catching centers to markets. Currently, Bay of Bengal Programme is playing a laudatory role in improving the status of fisherwomen, focusing on training, awareness, saving and credit schemes and promotion of alternative income generating schemes. The programme needs expansion and wider coverage.

3.1.27.0 Aquarian Reforms

3.1.27.1 There is a need for a comprehensive set of Aquarian Reforms in order to foster the sustainable and equitable use of both coastal and inland waters for capture and culture fisheries. Introduction of Aquarian Reforms to help the fishers and the spread of fish enterprises based on the principle of gender and social equity as well as ecology are long overdue, even though concerns have been voiced in various fora over time. These reforms would inter-alia consist of leasing policy for major inland water resources like ponds, reservoirs and river system etc, as well as coastal areas for aquaculture, water tariff at concessional rate at par with agriculture, power tariff again at par with agriculture for small and marginal fishers, insurance against accidents/livelihood threatening events, enforcement of close season to permit sustainable fisheries in river system, the reservoirs and ponds. Further, since feed is a major component of the expense on aquaculture and in pond and reservoir fisheries, the taxes and custom duties should be minimum in order to sustain poor fishers who are suffering from dwindling catches. In addition, the open access system in marine fisheries has also caused severe stress on sustainability of fisheries resources and this must be regulated in a sustainable way so that the implementation is not coercive but consensual. It is essential to foster harmony in the use of living aquatic resources by artesenal fisher men operating catamarans and commercial
families operating mechanised fishing boats and trawlers. The major aim of the Aquarian policy should be the conservation of living aquatic resources, sustainable use, equitable sharing of benefits and harmony between artesianal and mechanised fishing.

3.1.27.2 While the elements of **Aquarian Reforms** are fairly obvious, their implementation over the years has been less than satisfactory for various reasons. It is suggested that the DAHDF should set up a small Committee, which should go into these elements keeping the requirements of gender and social equity and ecology in view and give its recommendations on the lines of land reforms, for adoption by the states after consultation with all stakeholders.

### 3.1.28.0 Fisheries in North Eastern States

3.1.28.1 Fisheries resources of the seven landlocked North Eastern States viz. Arunachal Pradesh, Assam, Meghalaya, Mizoram, Manipur, Tripura and Nagaland are broadly of four types:

i) Rivers and streams; (18,968 km)

ii) Reservoirs (42,782 km);

iii) Beels/lakes (1,43,491); and

iv) Ponds (42,782 ha).

3.1.28.2 The average fish catches in these states from riverine resources range between 26-80 kg/ha, in case of ponds, it is 400-1300 kg/ha and in case of beels it is 30-180 kg/ha. There is a quantum rise in fish seed production in these states. Production of table size fish has shown only a nominal increase. In view of widespread and extensive waters in the form of rivers, lakes, beels, these states have tremendous potential for raising fish production. Besides the 19,000 km run of river Brahmaputra, the most important resource in the region is lakes/beels. Arunachal Pradesh offers immense scope for production of trout culture, running water fish culture, integrated fish farming, and ornamental fisheries. The priority areas for Assam are undertaking programme on integrated farming, exploitation of fisheries potential of beels, enhancement of fish production in ponds, freshwater prawn culture.

3.1.28.3 In case of Meghalaya and Nagaland, the scope exists for production of cold water fishes, development of lakes/ reservoirs/ beels and integrated fish farming.
Tripura has all type of water resources viz. rivers, beels, reservoirs etc. and a tradition of fisheries and the activities relating to integrated farming and ornamental fishery could be intensified for employment generation and higher production.

3.1.28.4 There is tremendous potential for development of mahseer and trout fisheries in the States of Meghalaya, Arunachal Pradesh and Nagaland. Hatcheries on the lines of J&K and HP could be constructed and rainbow trout farming could be promoted in the government. as well as private sector.

3.1.28.5 Lakes and beels having water spread of over 1.46 lakhs hectares constitute a major resource for fisheries exploitation. In view of their productive potential, with little efforts on management practices coupled with stocking, the average fish production in lakes and beels could be given a quantum raise. The scope for integration of fisheries with pig, poultry and duckery is immense in the region. 15-20% of paddy cultivation is being done in the region in low-lying area and in which deep water paddy is grown without pesticides. Such areas are ideal for paddy cum fish culture. The upland pockets of Meghalaya and Arunachal Pradesh are highly suitable for establishing running water fish culture units with cultivable species like trout and mirror carps.

3.1.28.6 Extension/ training activities require strengthening in all the North Eastern states. There is a need to raise teams of trained officials for providing support to extension.

3.1.28.7 ICAR centers for the North-East in Barapani should undertake a major programme of seed and brood stock production for species suitable for the North-East, particularly ornamental fish, at affordable rates.

3.2.0 Marine Fisheries

3.2.1 An Overview

3.2.1.1 The fishery wealth of India has enormous potential to provide livelihood and nutritional security to the large population of the country. Sustainable development of marine fisheries requires a sound combination of good management practices and conservation measures. These *inter alia* include sustainable harvesting of resources following eco-friendly fishing methods, enhancement of over-exploited resources through closed season and closed areas, rationalization of the existing fishing effort,
improved infrastructure for landing and berthing of fishing vessels, monitoring, control and surveillance, promotion of resource-specific fishing in the deep sea and a safety and security net for the small-scale fishermen. While agriculture provides food security, fisheries provide nutritional security to the country and both of them should be treated at par with each other in all development programmes.

3.2.1.2 The marine fisheries resources of the country comprise a long coastline of 8118 kms and an equally large area under estuaries, backwaters, lagoons, etc highly amenable for developing capture as well as culture fisheries. After declaration of the EEZ in 1977, the area available to India is estimated at 2.02 million sq. km, comprising 0.86 million sq. km on the west coast, 0.56 million sq. km on the east coast and 0.60 million sq. km around the Andaman and Nicobar Islands. With the absolute right on the EEZ, India has also acquired the responsibility to conserve, develop and optimally exploit the marine living resources within this area.

3.2.1.3 The harvestable potential of marine fishery resources in the EEZ has been estimated at about 3.921 million tonnes. An estimation of the depth-wise potential shows that about 58.0 per cent of the resources are available in 0-50 meter depth, 35 per cent in 50-200 meter depth and 7.0 per cent in depths beyond 200 meter (Table 9).

3.2.1.4 The marine fishing fleet comprises about 0.281 million traditional craft (including about 44,578 motorized traditional craft), 53,684 mechanised craft and about 170 large fishing vessels of 21 meter overall length (OAL) and more. As seen by the number of traditional craft and small-mechanised vessels, the major fishing activities are still concentrated in the areas within the 0 to 70-80 meter depth zone. As compared to the west coast, concentration of traditional craft (including motorized) is more on the east.

coast (about 57 percent of the total). In the case of mechanized vessels, the trend is reverse. The scale of mechanization is also reflected in the total fish landings of the two coasts.

3.2.2 Fish Production and Trend

3.2.2.1 It has been generally recognised that the Indian Ocean has the best-developed fisheries, but coastal resources in this ocean are under stress in many areas and require effective management, even though the potential for expansion may exist offshore. In India, while inshore waters have been almost exploited to the sustainable levels, the contribution from deep sea has been insignificant. The current (2003-2004) annual fish production has been estimated at 6.4 million tonnes (mt) – 3.0 mt from the marine sector against a potential of 3.9 mt and 3.4 mt from the inland sector against a potential of 4.5 mt (Table 10).

Source: Ministry of Agriculture, Government of India

3.2.2.2 The growth in marine fisheries production over the recent years has been rather slow (an average of 2.19 per cent during the period 1991-1992 to 1999-2000) as compared to the inland fisheries (average of 6.55 per cent during the corresponding period). Gujarat continues to be the leading producer of marine fish followed by Kerala, Maharashtra and Tamil Nadu. Penaeid shrimps, which dominate the export front, are at
their optimum exploitation levels, whereas tuna and cephalopods are the two least exploited fisheries owing to limited operational range of the majority of the present fishing fleets and also the lack of suitable technology. Several other species in the continental shelf are exploited only up to 70 - 80 m depths.

3.2.2.3 The export of marine products in terms of value registered a level of Rs. 60,920 million in 2003-04 against Rs. 17,674 million during 1992-1993. Frozen shrimp continued to be the largest item in terms of value. Shrimp contributed 31.50% in volume and 65.88% in value of the total export of marine products from India. USA continued to be the single largest market for Indian marine products in value terms, with Japan in the second position. Export to South East Asian markets have shown an increase over the years and several minor markets like South Africa, Tunisia, Poland, Ukraine and Hungary have emerged, showing a positive growth.

3.2.2.4 The growth rate in total fish production has been around 4.12 per cent per annum during the nineties. The inland sector has witnessed a much higher growth rate of 6.55 per cent as against 2.19 per cent in the marine sector during the corresponding period. Keeping in view the slow growth rate achieved in the marine sector and stagnation in the near-shore waters, a growth rate of 2.5 per cent has been proposed during the Tenth Plan. To even achieve this growth rate, it will be necessary to implement sound programmes for exploitation of the deep-sea resources.

3.2.3 Issues and Approach to Development

3.2.3.1 Entry 57 of List 1 of Seventh Schedule of the Constitution specifies Fishing and Fisheries beyond Territorial Waters as a Union subject, whereas Entry 21 of List II speaks of Fisheries as a state subject. Reading both the Entries together, it follows that control and regulation of fishing and fisheries within territorial waters is in the jurisdiction of the state, whereas beyond the territorial waters, it is the exclusive domain of the Union. Therefore, management of fishery exploitation in the EEZ requires close coordination between the centre and the states.
3.2.4 Coastal Marine Fisheries

3.2.4.1 India’s EEZ comprises different depth zones: 0-50 metres extending to 0.18 million sq. kms; 50-200 metres extending to 0.27 million sq. kms; and 200 metres and beyond extending up to the limits of the zone, 1.57 million sq. kms. Presently, 25 per cent of the present production is by the artesenal sector and 74 per cent is from small-motorized boats. Only about one per cent is from the deep-sea fishing vessels in operation. Fish production has increased over the years with the motorization of traditional craft and introduction of mechanized boats in the traditional sector, as well as by the diversification of fishing effort beyond 50 meters depth.

3.2.4.2 Fishing effort is currently concentrated in the 0 to 80-90 m depth zone. Approximately 99 per cent of the landings are obtained from this zone. While inshore waters have been almost exploited to the sustainable levels, the contribution from the deep sea has been insignificant. The fish production from near-shore waters (up to about 90 meter) has reached its optimum yield levels and has been stagnant for some years leading to pressure on the coastal fin and shellfish resources and regular conflicts between traditional and mechanised sectors. Although the Marine Fishing Regulation Act (MFRA) promulgated by the coastal states and the union territory of Lakshadweep provides zones for different categories and sizes of fishing vessels to operate in demarcated areas, this seldom takes place due to inherent weaknesses in the Act. Central Government should assist states to rectify these weaknesses.

3.2.4.3 India faces considerable difficulties in the development and management of its marine fishery resources for a host of reasons. The Indian subcontinent covers a vast region with long coastlines and different ecosystems, both on land and in the sea. The fishery resources are diverse, as are the fishery technologies and systems. Artesenal and small-scale fishermen operate from thousands of landing places dispersed along the coast and live within socially and culturally disparate communities. Responsibilities and programmes for fisheries management and development are split between the Union government and state/union territory governments, which differ in their policies, programmes and approaches. Central Board of Fisheries should meet at least twice a year to sort out these difficulties in the interests of all concerned.
3.2.4.4 A sizable population of the marine fisher folk living in the 3600 fishing villages are socio-economically backward due to poor literacy, total dependence on fishing, unstable income, extravagant spending on alcohol, health hazards and risky life in the sea without adequate insurance cover for family. They are also victims of cyclone, tsunami and other natural calamities. Several welfare schemes of the Government have helped only a small percentage of the population. Therefore, the programme of poverty alleviation of the families of nearly seven million fishers has to get top priority in the fisheries development programme.

3.2.4.5 Recent trends in both artesenal and small-scale fisheries in the country have been disturbing and indicate the need for implementation of sound management programmes. Several fish stocks are being over-fished. The loss in terms of harvest of juveniles is very substantial. Trawlers and Ring seiners cause maximum destruction of juvenile population followed by mini trawlers and purse seiners. In fact, such management for the coastal marine fisheries is long overdue. The catches and earnings of fisher folk have been declining. Resource scarcity and the dearth of new income opportunities have combined to make life difficult for small-scale fisher folk. The Government should take all steps to reduce juvenile harvest through introduction of appropriate fishing gears as developed by CIFT. Considering the large-scale exploitation of juveniles and discards by the trawlers, the cod end mesh size of trawl with square shape should be increased to 30 mm.

3.2.4.6 Introduction of mechanized boats and motorization of traditional boats have caused extended fishing operations. This has also increased the fishing pressure beyond recovery of certain standing stocks and depletion of resources is noticed in many fisheries. Therefore, restriction and regulation in the operation of mechanized/ motorized fishing vessel is required in a phased manner to curb the excess fishing effort. Further, mechanized fishermen and traditional/non-mechanized fishermen should have clearly demarcated zones for fishing to avoid clashes.

3.2.4.7 The open access nature of marine capture fisheries is one of the major reasons for depletion, economic waste and conflict among user groups. Without adequate control over access, these consequences will become increasingly sever and further impede the sustainable management of fishery and the resource. With an open access, no catch limits have been set on effort or the catch.
3.2.4.8 The restriction of fishing effort could be in the form of restriction in the number of vessels, number of days or hours at sea, engine power, size of the fishing gear, fish holding capacity, etc. Fishing pressure on over exploited fishery resources such as shrimp in the inshore waters has to be drastically reduced. Restriction in areas for resources specific fishing, prolonged seasonal closure to allow recovery of over-fished species, prevention of fishing juveniles and spawners during breeding/spawning season should be introduced. Since the monsoons trigger breeding and spawning and monsoon effects vary from place to place and year to year, a close monitoring of resources is vitally required to make a regular fisheries forecast. Until such fisheries forecast system is introduced, the present uniform closure of fishing in all maritime states and UTs could continue.

3.2.4.9 To optimise the fishing fleet size, a National-Level Review Committee was constituted in 1997 to study the size of the present marine fishing fleet in India vis-à-vis the harvestable potential and gives recommendations on the fishing effort that need to be deployed. The Committee concluded, after discussion with experts and with coastal states and the union territories that the mechanized fishing fleet, in the size range of 8.0 to 15.0 m over-all length (OAL), has attained optimum strength and no fresh entry should be allowed. However, 700 new-generation resource-specific vessels, about 18m OAL, including trawlers and gillnetters-cum-longliners, could be added to the fleet to tap resources in the EEZ beyond the 50 m depth zone. This step also vindicates the recommendation of the Committee on Deep Sea Fishing set up by the Union Government in mid-nineties. The recommendations of the Review Committee on Optimization of Fishing Fleet need to be implemented at the earliest to sustain the coastal fisheries.

3.2.4.10 At present, the mechanized fishing vessels alone are licensed. The system of licensing needs to be extended to motorized and non-motorized craft as well. Licensing will be helpful to maintain an inventory of all categories of fishing vessels. Another management option that has been considered for this area is to encourage small trawlers to diversify into fishing activities that can be practised further offshore, in order to reduce overcrowding in inshore waters and reduce the pressure on the fish stocks. However, few fishermen are equipped for such ventures, and there is a need to provide support to this category as also technical information on the availability of resources or the best fishing methods with which to target them. Assistance from the Food and
Agriculture Organisation can be sought to obtain suitable technology for the Indian conditions.

3.2.4.11 Gear employed for exploitation of demersal resources, particularly the bottom trawl, is being used excessively. The trawlable biomass appears to be overexploited and a reduction in the trawl effort is necessary to sustain the demersal fishery. On the other hand, the gear employed for the exploitation of pelagic resources is either underused or not used at all. Considering the biomass abundance of plankton feeders, such as the small pelagic species along the southwest coast, pelagic and mid-water trawling should be encouraged.

3.2.4.12 On a fair estimate, 70 per cent of the operational cost of a mechanized fishing vessel is accounted for by fuel cost alone. Therefore, one of the prime requirements of the fishing industry is development, demonstration and popularization of fuel saving designs of fishing craft, fishing gear and methods. Studies on the energy efficient hull designs for fishing vessels for reduced power requirements and their effect on vessel motions and manoeuvrability at sea, are required on a continuous basis. Development of deep-sea hull designs in FRP and aluminium for fishing vessels is also essential keeping in view the scarcity of timber.

3.2.4.13 The existing regulatory policies restrict fishing season, fishing areas and the mesh size of gear. However, there is no monitoring and surveillance system available with the concerned implementing organizations. Voluntary compliance by the fishermen to operate in the areas allotted to them is totally absent and encroachment by the larger mechanized vessels in the areas demarcated for the artesenal craft continues. The Central Government has now proposed to introduce a Vessel Monitoring System (VMS), which is expected to resolve the problem. Implementation of a sound monitoring, control and surveillance system including the VMS should be implemented at the earliest. The demarcation of the areas reserved for the small-scale sector also needs to be done on a priority basis. Similarly, the Central Government should also consider providing a fresh model bill to the states/union territories to enable them to revive their MFRAs on the basis of their present requirements and also global initiatives to which India is a signatory.

3.2.4.14 In the wake of the Tsunami disaster, substantial support both financial and
infrastructural, has come to the affected fishers and their villages in the form of fiberglass boats and huts etc. The fear has been expressed in some fora that the number of artesenal boats in the affected coastal areas would in fact go up since some fishers may even use the damaged boats after repair in addition to the new boats received by them. This would further increase the fishing intensity and may result in still lower catches and unsustainable stock. States must therefore immediately embark on a programme of registration of all boats in the coastal areas, in order to assess the situation and adopt suitable policies in consultation with all stakeholders to ensure a sustainable fishing fleet commensurate with availability of landing and berthing facilities.

**Box - 9**

**Self-Help Groups in Fisheries (Tamil Nadu)**

The Southern Districts of Tamil Nadu have witnessed significant increase in the number of fisherwomen Self Help Groups (SHGs). Punnakkayal village has the largest number of SHGs in an Indian village with over 50 groups consisting exclusively of fisherwomen.

Today, there are several examples of successful fisherwomen SHGs in the region and their experiences need to be promoted in the other states also. Examples: The fish market at Neelankarai is managed by fisherwomen belonging to 12 SHGs. The management practices established by this group demonstrate their efficiency and unity. Similarly, the SHGs formed by fisherwomen in Vellapatty village in Tuticorin has enabled its members to conduct individual business involving a wide range of activities, including fattening of crabs for sale in the local market. These SHGs also have good linkages with the NGOs who have helped them in the promotion of their business.

**3.2.5 Potential Fishing Zones (PFZs)**

3.2.5.1 Remote sensing can play a significant role in dissemination of information on potential fishing grounds and also assist in judicious exploitation, conservation and management of marine resources. The imageries received by the National Remote Sensing Agency (NRSA) at Hyderabad are used to derive the sea surface temperatures and interpreted to identify the PFZs. These identified PFZs are informed to the fishermen on a day-to-day basis. Ground truth surveys have indicated substantially higher fish catch rates in the PFZ areas than in the non-PFZ areas, especially for small pelagics. Encouraging and supporting development of local facilities for receiving, processing and broadcasting the PFZ data will be of great help to the small-scale fishermen.
3.2.6  Co-management of fisheries and stakeholder consultations

3.2.6.1 Fisheries cannot be managed effectively without the cooperation of fishermen. The delegation of fisheries management to the local fishing committees will be more effective than the direct management by the Government. Once the community is involved in the formulation and implementation of management measures, better acceptability and compliance can be expected. Co-management makes maximum use of indigenous knowledge and expertise to provide information on the resource base and to complement scientific information for management. The potential advantages of a co-management include effectiveness and equity. It can be more economical in terms of administration and enforcement than the present centralized systems. It provides a sense of ownership over the resource, which makes the community more responsible for long-term sustainability of resources.

3.2.6.2 The vital interest of artisanal fishing sector should be protected. Stakeholder consultations should be held at regular intervals to bring them into the management process and ensure a balance in exploiting fishery resources for long-term sustainability. Such consultations should include discussions on new policy formulations, amendments to the existing policies and other important issues as considered necessary.

3.2.6.3 We are already in the new millennium and at a very crucial juncture of marine fisheries development. Many landmark decisions have been taken in the near past (e.g. closed season during monsoon months, optimization of the fishing fleet, revalidation of the harvestable potential) and their implementation is likely to bring radical changes. Restricted access to marine fisheries is being talked about more loudly than in the past. In April, 2005 the Government of India has also conducted a census of craft, gear and other attributes of economic significance for the entire coastline (including the two groups of Islands). This exercise is also seen as a benchmark for the millennium and would be valuable for planning and development of the marine fisheries sector in the country. This should be utilized effectively.

3.2.7  Protection of coastal fishery resources (near shore and estuaries) for a sustainable fish production

3.2.7.1 Coastal zone is the vital bridge between terrestrial and marine aquatic ecosystem. It is considered as the most productive ecosystem on earth in terms of biological
production since it accommodates rich biodiversity in estuaries, lagoons, inter tidal zone, coral reefs, mangroves and wet lands which are acting as breeding and spawning grounds. Since the coastal fishery resources depend heavily on the coastal zone ecosystem, their protection is of paramount importance, through involvement of local communities.
Appropriate coastal zone management and development of the ecosystem in a holistic manner is critical for the sustainable management for the fisheries and livelihood of fishers particularly the traditional fishers and other stakeholders. The M S Swaminathan Committee to review Coastal Regulation Zones Notification 1991 has submitted its report in February, 2005 and has developed the following 12 tasks guiding principles which should govern future decision on Coastal Zones Management:

1. Ecological and cultural security, livelihood security and national security should the cornerstones of an integrated coastal management policy.
2. The coastal zone is including an area from 12 nautical miles including sea-bed and inland tidal water bodies etc., should be taken up for an integrated, cohesive, multi-disciplinary and multi sectoral coastal area management and regulatory system.
3. Regulation, education and social mobilization should be the three major components of a participatory and a sustainable Coastal Zone Management Strategy and Panchayati Raj institutions in coastal area should be fully involved in the educational and social mobilization programme.
4. The protection and sustainable development of the marine and coastal environment and its resources should be in conformity with international law. Every effort should be made towards ensuring an Integrated Marine and Coastal Area Management as prescribed in the 1995 Jakarta Mandate under the 1992 Convention on Biological Diversity.
5. Coastal regulation needs to be based on sound, scientific and ecological principles and should safeguard natural and cultural heritage. Heritage sites need particular care. Birds sanctuaries and parks and breeding ground of migratory birds should be protected.
6. The precautionary approach should be used where there are potential threats of serious or irreversible damage to ecologically fragile critical coastal systems and to living aquatic system.
7. Significant or irreversible risks and harm to human health and life, critical coastal systems and resources including cultural and architectural heritage would be considered unacceptable.
8. Ecological economics should underpin economic activities.
9. Coastal policy and regulations should be guided by the principles of gender and social equity as well as intra-generational and inter-generational equity. All stakeholders should be involved in decision making. Precious biological wealth coming under Marine Biosphere Reserves should be managed by Trusteeship mode.
10. Coastal protection and bio-resources conservation policy should be guided by techno economic efficiency, the precautionary approach, “polluter-pays” principle and “public trust doctrine”
11. Those engaged in hazardous dangerous coastal activities should bear the liability to compensate the victims of marine pollution and fish contamination and should also bear the cost of restoring the coastal environmental degradation. The onus should be on them for demonstrating that their developmental activities are environmentally benign. The principles contained in Biodiversity Act (2002) should be applied to coastal bio-resources management involving concurrent attention to conservation, sustainable use and equitable sharing of benefits.
12. The regeneration of mangrove wetlands, coral reefs and sea grass beds as well as promotion of coastal forestry and agro-forestry will confer both short and long term ecological and livelihood benefits. National coastal bio-shield movement along the coasts of the mainland of India and islands should be initiated as a priority task under National Rural Employment Guarantee and Food for Work programmes. Short term commercial interests should not be allowed to undermine the ecological security of our coastal areas.

Thus, coastal zones management requires cohesive, multi-disciplinary approaches as well as multi-dimensional vision. Sustainable human security in all its dimensions - ecological, economic, ethical cultural and human well being, in terms of the health and happiness both for men and nature should be the goals of an enlightened Coastal Zone Management Policy.
3.2.8 Deep Sea Fisheries

3.2.8.1 Besides shrimp aquaculture, fishing rights and responsibilities in the deep sea fishing sector have been the most debated issue since the mid-nineties and various user groups have different opinion on the modalities of harnessing the marine fisheries wealth, especially from the deeper waters. At the outset let us recognise the fact that traditionally India has had no entrepreneurship in the deep-sea fishing. Historically, the coastal communities have fished in the near-shore waters, using artesenal methods, most of which are still in vogue today. In order to develop entrepreneurship and promote investment for greater exploitation of the marine fisheries, the Government has provided policy supports for the development of the industry from time to time. The Shipping Development Fund Committee (SDFC) was entrusted with the task of extending soft loans to the deep-sea fishing sector. Loans were provided to the extent of 95 per cent of the cost of the vessel and the debt equity ratio was 6:1. A number of Indian companies acquired deep-sea fishing vessels since 1975, but almost all of them were shrimp trawlers, which operated on the east coast in limited areas from Visakhapatnam. Less than half the numbers of these shrimp trawlers are in operation at present. Acquisition of deep sea fishing vessels was financed by SDFC till 1986. In a few cases consortium of nationalised banks also came forward to finance deep sea fishing vessels. Later on SDFC was wound up and SCICI took over its activities.

3.2.8.2 Another policy initiative taken by the Government of India was to introduce the charter policies of 1981 and 1986. Subsequently, for obtaining requisite technology for exploiting the deep-sea resources and exposing the Indian entrepreneurs to the latest developments in the field, the New Deep Sea Fishing Policy was initiated during 1991. The accent of the policy was on increasing fish production and acquisition of deep sea fishing vessels by the entrepreneurs through joint ventures, leasing and test fishing for technology transfer, since other nations had the requisite technology and the appropriate vessels for this purpose. The 1991 policy also came to an abrupt end after the Government accepted the recommendations of the Deep Sea Committee in September, 1995.
3.2.8.3 In retrospect, it could be said that of the many flaws these policies had, one major flaw was that they were restricted to the deep-sea sector. Policies of such exclusive nature created chasm between the small-scale sector (small mechanised & traditional vessels) and those licensed to fish in the deep sea. The growing fear of complete domination by the big brother gradually led to agitation, which ultimately culminated in rescinding the New Deep Sea Policy of 1991. Subsequently, the Government of India has approved a Comprehensive Marine Fishery Policy in November 2004, which includes important elements for the Deep Sea Fisheries. These must be implemented in a time bound manner and in full collaboration with the States. It is important to stress that the States must also be consulted and kept in the picture while licensing Deep Sea ventures for better control and harmony in the seas.

3.2.8.4 Of the many options to harness the deep-sea fishery resources, diversification of the existing deep sea fishing fleet and introduction of resource specific vessels for long lining, purse seining and squid jigging is absolutely necessary in the present circumstances. Mechanised vessels below 20m OAL necessitate major inputs in their design to not only increase their voyage but also facilitate bringing back the catch in as good condition as possible. The design of the boat, engine power, winch capacity, gears and cold storage facilities on board may have to be checked to equip them properly for offshore fishing. However, countries like Sri Lanka have successfully promoted the use of intermediate range of fishing vessels to fish in the deeper waters and thereby reducing pressure on coastal stocks. Introduction of modern fishing vessels in the intermediate range (15-19 m OAL) is also essential to exploit areas between 90 to about 150 m depth to harness both demersal and pelagic resources.

3.2.9 Empowering small-scale fishers for offshore fishing

3.2.9.1 Participation of small-scale fishers in offshore fishing is limited due to heavy capital investment and recurring expenditure. In this regard the fisher cooperatives/associations/groups should be assisted through bank loan and subsidy to enable them to take up offshore fishing. Assistance should be provided to engage carrier cum supply vessels to a group of fishers so that they can fish longer in the sea and the catch could be brought back in good quality at regular intervals through carrier vessels.
3.2.9.2 Our fishing effort around Andaman & Nicobar Islands and Lakshadweep Islands is negligible. Though these two groups of islands in the Bay of Bengal and Arabian Sea are located strategically to exploit oceanic pelagic fishery resources, no serious attempt has been made so far to develop a strong base for oceanic fishing. The resource potential of these islands in the Indian EEZ is estimated at 250000 metric tonnes and the present harvest is about 40 000 metric tonnes. Special cells should be set up in Lakshadweep and Andaman & Nicobar Islands, to exploit tuna and other oceanic pelagics. These fishing bases should be developed as in Maldives with mother fishing operation to harvest tuna and squid resources in the EEZ and beyond in the international waters. Oceanic tuna fishing should be the main focus for which all infrastructure facilities should be developed with adequate incentive for the Island fisherman cooperatives. Commercial fisheries development should be encouraged to allow private entrepreneurs to invest in Island fisheries.

3.2.9.3 Since mother ships are costly, the Govt. should position one mother ship in A&N Islands and other in Lakshdweep Islands, which could collect the catch of smaller boats and process them on boat for value addition/store the catch in refrigerated holds and thereby allow fishing boats to operate for longer periods without spoilage of fish. It is recommended that Rs. 10 crores should be earmarked for purchase of two mother ships.

3.2.9.4 Taking into account the harvestable potential for deep-sea resources, the first step is to fix the fleet size for different category of resource- specific fishing vessels. Once an optimum fleet size is fixed, the second step would be to arrive at a policy for acquisition and deployment of such vessels. In the absence of indigenous capabilities to construct resource- specific vessels and the activity also being capital- intensive, equity participation with sound guidelines may have to be considered. Coupled with this, adequate support through post- harvest infrastructure and marketing would also be necessary. Some of these aspects are discussed in greater details in the following paragraphs.
Fishermen Cooperatives (SIFFS, Trivandrum)

The South Indian Federation of Fishermen Societies (SIFFS) originated through the intervention of NGOs in the artesanal fishing sector during 1970s and 1980s. Starting as an apex body of societies of Trivandrum district, SIFFS in its present form comprises a three-tier structure. The three core activities of SIFFS include (i) marketing of fish caught by members, (ii) providing credit for renewal of fishing equipment and (iii) promoting savings. Some of the major interventions of SIFFS include:

**Boat Building**

SIFFS pioneered the introduction of marine plywood boats in 1982. Since then, it has been playing a major role in the promotion of marine plywood boats in three districts on Southwest coast of South India. The activities under this programme include (i) setting up boatyards to manufacture different models of boats and undertake repair works, (ii) conducting research and development on designs of boat models and materials for boat building and (iii) providing training in boat building and maintenance. Today, SIFFS is a leading player and a leader in plywood boat building market in South-West Coast of India.

**Outboard Motors**

SIFFS recognises the link between OBMs and plywood boats and, therefore imports outboard motors and spare parts for distribution to the beneficiaries at affordable prices. Today, SIFFS is the country dealer for Suzuki marine products, and a leading importer of OBMs and spares in South India. Over the years, SIFFS has also kept pace with rapid increase and spread of motorised craft through setting up of OBM service centres and spares parts outlets for sale and maintenance works.

**Fish Marketing & Ice Plants**

Fish marketing has been one of the major areas of intervention of SIFFS and has been exploring new areas for marketing of both fresh and processed fish through trials and experiments in export market. Quality improvement programme is an area of priority for SIFFS now. SIFFS has also initiated marketing of fish in the domestic sector through a retail shop in Trivandrum. The shop aims to serve as a channel to sell the surplus fish procured for the export purpose.

SIFFS is an excellent example of cooperative endeavour coupled with modern marketing enterprise, which can be replicated in other states also.

3.2.10 Post-harvest Infrastructure and Marketing

3.2.10.1 In India, approximately 67 per cent of the total fish production is consumed in fresh form as per the available data. Nearly 6 per cent is used for reduction into fishmeal. Altogether 23 per cent is consumed in processed and preserved form that includes 16 per cent used for drying, 7 per cent for freezing and less than one-half per cent for canning- almost all of these under medium and small- scale sectors. As spoilage of fish starts right from the time it is caught, the proper storage, preservation and prompt disposal or transport services are essential. Various studies have from time to time
pointed to the high levels of wastage in the fishery due to spoilage. This is particularly acute during the monsoon, when up to 30 per cent of the catch could be lost. This is a vital area to be addressed, and may result in increased economic returns to those dependent on the fishery without any increase in fishing effort. Therefore, strengthening of post-harvest infrastructure such as storage facilities, ice plants, cold chains, roads and transportation, etc., as well as effective marketing system in identified areas are the key requirements for the development of this sector. This would ensure higher profit margins to the producers enabling faster fisheries development.

3.2.10.2 Since fish is subject to rapid deterioration in quality in view of the generally hot climate in India and the inadequate cold chain, it is necessary to ensure quality literacy amongst fishers in order to ensure appropriate value realization for them and also to protect the health of the consumers. This could be achieved by regular programmes of awareness generation/knowledge dissemination on the pattern of the good work done by National Egg Coordination Committee.
Corporate Sector in Aquaculture and Seafood Processing  
(The Waterbase Ltd, Nellore, Andhra Pradesh)

The Waterbase Limited (TWL) is the largest and the only integrated aquaculture unit in India located in the heart of shrimp country at Nellore, Andhra Pradesh. The Company began operations in 1993 and is today a US$18 million company (Rs. 1 billion) with facilities that comprise a shrimp hatchery, feed plant, grow-out farms, and an ultra-modern process plant. Black Tiger (P. monodon), White (P. indicus) and Scampi (M. rosenbergii) are raised in the farms of the Company. The Company sells shrimps in various forms such as cooked, beheaded, deveined, etc depending on the customer requirements. Apart from its own stock of shrimp, the Company also sources it from other farmers to meet orders. The Company follows HACCP guidelines and is among the few Indian companies that have FDA approval for export of marine products to USA.

The Company exports shrimp in different forms to the quality-conscious markets of Japan, USA, and Europe. It has a 50: 50 joint venture with Handy and Son of US. This JV is exporting pasteurized crabmeat that is considered a delicacy in the West. The Company has also made a retail foray with a specialty seafood restaurant in Bangalore called Tiger Bay and proposes to take this concept to other cities soon. The Company has recently entered into an R&D alliance with INVE of Belgium.

The Government of India has recently permitted the Company to import P. monodon broodstock from Myanmar waters for breeding and also for initiating a long-term programme on domestication of tiger shrimp. The Company is also in the process of perfecting the technology for breeding and raising of mud crabs (Scylla serrata), which have a lucrative domestic and export market.

M/s Waterbase Ltd is today the only corporate sector player in shrimp farming and its integrated unit in Nellore is an excellent example of corporate sector’s contributions to the development of seafood industry in general and shrimp farming in particular.

3.2.11 Assistance to women fish vendors

Women fish vendors largely do retail marketing in the marine sector. Over the years, the supply of fish to women vendors is on the decline and they face several other hardships in selling fish, which is a highly perishable commodity. Schemes to promote retail marketing of fish in hygienic conditions should aim at providing assistance to women fish vendors, especially with regard to containers for carrying fish, transportation facilities, etc. Self-help Groups comprising women fish vendors should also be assisted in setting up of hygienic retail outlets with facilities for keeping the product in chilled/ refrigerated conditions. Such schemes will be helpful in sustaining their livelihoods and ensuring quality fish to the consumers.
Hygienic Marketing of Fish in the Domestic Sector
(Chennai, Kochi)

Hygienic marketing of fish and fish products in the domestic sector has been a neglected area. Despite several attempts by the Central and State Governments, no tangible results could be achieved. However, in recent years retail marketing of fish and fish products (mainly marine fish) by the private sector has been successful and retail shops have been set up in Chennai, Kochi, Bangalore and Hyderabad. While some of these retail outlets are linked to processing units, others have been set up by enterprising youth. A visit to some of the retail shops in Chennai or Kochi will show the difference it makes to the quality of the product.

This is a significant development and there is a need to promote this initiative, especially through the private sector in the other states also.

3.2.11.2 In the marine fisheries sector, the Central Government has been implementing a central sector scheme and a centrally sponsored scheme since 1964 to provide infrastructure facilities for landing and berthing of mechanised fishing vessels (MFVs), traditional and motorised fishing craft and deep sea fishing vessels. At the end of the First Five-Year Plan, there were 863 mechanised fishing vessels operating along the Indian coast. Presently, there are about 54,000 Mechanised Fishing Vessels and 44,578 motorised fishing crafts. The landing and berthing facilities commissioned so far can only meet the needs of a quarter of the total fishing fleet, resulting in over-crowding and a host of other accompanying problems. Therefore, there is an imperative need to develop more fishing harbours and landing centres to meet the requirements of the existing fishing fleet.

3.2.12 Upgradation of fishing harbours and fish landing centres

3.2.12.1 Most fishing harbours in the country are not properly maintained, due to lack of management and inadequate revenue collections. After the harbours are commissioned, the responsibility of maintenance and management is vested with the user agencies/ cooperatives/SHGs. The income should be ploughed back for management and maintenance of the centres. However, adequate revenue is being collected regularly in only a few fishing harbours. In some, the revenue collected is too meager for proper management and maintenance. Perhaps, more Aqua shops for catering to the
requirements of the fisher folk in terms of fishing gears/boats etc. along with repair shops for these could be setup to increase revenues. NABARD already has a scheme for assisting technical graduates for setting up Agri-Business Clinics and the scheme could be utilized by fisheries graduates also to set up Aqua shops. Qualified professionals are required to set up these shops due to stringent hygienic requirements under HACCP.

3.2.12.2 The hygiene and sanitation conditions in most of the harbours and fish landing centres are below the normal specifications. This is partly due to inadequacies in the design and construction of the facilities and partly due to poor maintenance. The user groups are largely responsible for the poor state of hygiene and sanitation. Accepted standards of hygiene and handling of fish demand that these facilities be maintained strictly, and that contamination of fish be kept down to a minimum. The fishing harbours in India need to be modernised to meet minimum international standards necessary for fish quality assurance\(^2\). Special design approaches need to be adopted to meet the requirements of standards laid down by Hazard Analysis and Critical Control Points (HACCP) and ISO 9000. If these requirements are not met in the immediate future, the marine products exports may face trade restrictions, since most of the importing countries have stringent hygiene and sanitary conditions. Further, a greater awareness is necessary for the fisher folk on the importance of hygienic handling and preservation of fish as also personnel hygiene in improving the quality of landed fish and prevention of loss and wastages.

3.2.12.3 It is necessary to undertake an ambitious programme to construct minor harbours and fish landing centres which would directly benefit the marine fishers through better handling of fish and safer landing leading to better value realization besides improving the prospects of exports through compliance with the requirements of importing countries. This should be in the central sector considering that the present scheme has had limited success because of its insistence on state share. It is estimated that over the seven-year period culminating in the end of the Eleventh Plan, a total of 20

\(^2\) For modernisation of the existing facilities, the Ministry of Agriculture has allocated budget in the Ninth Five Year Plan @ Rs. 4.0 million for a minor fishing harbour and Rs.2.0 million for a fish-landing centre. This would be a one-time assistance to the states/union territories.
minor harbours each costing Rs. 12 crores and 40 fish landing centres each costing Rs. 3 crores would be required, on a conservative estimate.

3.2.12.4 In addition, greater attention would have to be paid to the existing minor fishery harbours and fish lending centres, which have been constructed over the years and are now becoming difficult to use because of the heavy siltation. It is estimated that at least 50 existing fishing harbours/landing centres need maintenance dredging. Dredging operations can go long way for improving the capacity and utility of these centres. These centres because of their smaller size require special Dredgers; a small Dredger was received as a gift from the Government of Japan a few years back and has been in operation on the Kerala coast with good result. However, the country still needs three more Dredgers, two for the Eastern coast and one more for the Western coast. One method could be to acquire these through normal tenders and operations through a Central agency. Other solution could be to outsource the work of Dredging to private operators with grants from the Govt. of India of Rs. 20 crores for a limited period of five years to the states so that they could afford the Dredging operations. This would save capital costs and operation and maintenance expenses. Since the private sector does not seem to have such small sized Dredgers presently, it may be more practical to acquire these three Dredgers at a cost of approx. Rs. 30 crores.

3.2.12.5 The development of deep-sea fishery industry is of concern to the entire marine fishery sector because it would have considerable impact on the management of near-shore fisheries, shore-based infrastructure utilisation and post-harvest activities, both for domestic marketing and export. Selected fishing harbours should also be equipped with storage facilities for sashimi grade tuna. To avoid over-capitalisation and to ensure a cautious growth of the infrastructure as well as the investments, a rationalised approach will be essential in determining the number and size of fishing vessels, their resource-specific gear and operational equipment as well as technology to be made available either indigenously or through foreign collaborations. The Master Plan must be updated after due consultation with states keeping factors like potential, fishing fleet and export earnings in mind.

3.2.12.6 Lastly, it would be desirable to set up a Central Fishery Harbour Development Authority, which could comprehensively manage the Minor Fishery
Harbours and Fish Landing Centres in terms of construction, management, maintenance and dredging etc., in consultation with the States and the stakeholders. DAHDF should prepare a proposal for a law on the subject after consulting the States etc. so that harbours and fish landing centres could be managed more professionally.

**Box - 14**

**Marine Mussel Farming (Kerala)**

Marine mussels form one of the most dominant cultivable species all over the world. In India, two species of marine mussels (green mussel - *Perna viridis* and brown mussel – *P. indica*) support a traditional sustenance fishery. However, in recent years, the increasing demand for mussels (especially in northern Kerala) has enabled farmers in north and central Kerala to adopt commercial-scale technologies for mussel farming. More than 450 families in Kasargod, Kannur, Kozhikode, Thrissur and Malappuram are now proud owners of mussel farms.

The technologies for mussel farming have been developed by the Central Marine Fisheries Research Institute, Kochi and include rack, long line and raft methods.

The Malabar Coast of Kerala has now become the centre of mussel farming in India producing about 4,000 tonnes during 2004-05. On an average the mussel farmer is earning about Rs. 6,800 per season. Based on the success of this activity, women SHGs have adopted mussel farming in the back waters adjacent to their houses and the Banks are providing loans ranging between Rs. 8,000 – 9,000 per member of the SHGs. The Government of Kerala also provides financial support through DWCRA and IRDP to promote mussel farming.

### 3.2.13 Mariculture/ Sea Farming

**3.2.13.1** Mariculture provides immense opportunities for significantly increasing food production, employment, income and foreign exchange. Given the wide spectrum of cultivable species and technologies available, the long coastline and the favourable climate, mariculture is likely to generate considerable interest amongst the coastal population in the country. At a time when we speak of over-exploitation in the near-shore waters, limited access to capture fisheries and the need for diversification, mariculture can be one of the most appropriate alternatives. Technologies for a couple of species are presently available in the country and there is an urgent need for developing package of practices for many more commercially important species (e.g. sea bass, sea bream)

**3.2.13.2** However, with a possible scenario of large-scale mariculture activities taking place in the near future, it is likely that a situation akin to shrimp farming can be created where unplanned and a fast growth resulted in social conflicts and challenges to
the sustainability of the coastal environment. To avoid repeating the shrimp history, a systematic macro and micro-level survey of the entire coastline would be necessary, to prepare a comprehensive status on the area-wise suitability of the available mariculture technologies, carrying capacity of the ecosystem, social, legal and environmental implications, research and policy support, credit availability and other forward and backward linkages. A status report of this nature would essentially be a SWOT analysis and keep us in preparedness if mariculture activities were to be adopted on a larger-scale during the Eleventh Five-Year Plan. Meanwhile the States should have a liberal leasing policy for marine resources to encourage mariculture and avoid conflicts.

3.2.13.3 It may also be worthwhile to develop an All India Coordinated Research Project on Mariculture for transferring the technologies developed so far. Pilot-scale programmes are essential for standardisation and also to enable the end-users to familiarise with the technology, which has been tried successfully abroad.

3.2.13.4 Integrated capture and culture fisheries through seawater farming also offers an opportunity for fisher families particularly women. They can take to rearing of prawns and suitable salt tolerant fish species in canals along the sea coast, using low external input sustainable aquaculture (LEISA) techniques. Agro-aqua farms involving the concurrent cultivation of tree species and rearing of fish and prawn can be promoted to enhance income and employment and opportunities.

3.2.14 Seaweed culture

3.2.14.1 Seaweed cultivation is a profitable activity in the coastal areas and should be initiated as a poverty alleviation programme. Since these activities are new to fishers, demonstration with proper hand on training is necessary. Seaweed training programme, started in Ramnad, Kanyakumari and Tuticorin districts of Tamil Nadu for self-help women groups has given rewarding results. The banks have also come forward for financing seaweed cultivation with a guaranteed buy-back arrangement from companies making products from the seaweeds. Awareness creation, technology dissemination through training and assured marketing through Corporate Sector has created a momentum, which should be continued.
Seaweed Farming (Tuticorin, Tamil Nadu)

Seaweeds grow in the shallow coastal waters of the seas and are vital as a habitat for a variety of marine organisms. Seaweeds provide a valuable source of raw material for manufacture of health food, medicines, food additives, pharmaceuticals, etc. Some of the important products of seaweeds include agar, algin and carrageenan. The most common seaweeds in India available for farming include species of the Genus *Gracilaria*, *Gelidiella* and *Eucheuma/Kappaphycus*.

In Tamil Nadu seaweed cultivation is common in Rameshwaram, Pamban, Mandapam, Vedalai and Kilakarai areas, where cultivation is now being promoted through the SHGs. M/S PepsiCo India Holding (p) Ltd is also supporting the enterprise through buy-back arrangements.

Seaweed farming is a viable livelihood option for fisher-communities and has considerable potential in other states also. It is environment-friendly and has no adverse impact on the coastal ecology. The experience of the SHGs and other fisher groups in Tamil Nadu can be considered as a successful example for replication elsewhere in the country.

3.2.15 Artificial Fish Habitats and Artificial Reefs

3.2.15.1 It has been widely recognized that installation of Artificial Fish Habitats (AFH) and Fish Aggregating Devices (FADs) are helpful in increasing fish production. The AFHs and FADs allow congregation of fishes as they provide a congenial micro-clime in the ocean for shelter, food and nursery sites. Both AFH and FADs have been used extensively in Japan and Philippines. Large floating rafts called payaous are being used in some countries for exploiting tunas in the distant waters. Modern payaous are equipped with radar, reflectors and solar powered lights and are anchored in deep waters. Such rafts are now also becoming popular among the fishermen of Tamil Nadu and floating rafts installed about 100 km off Nagapattinam have helped fishermen in increasing their catch of oceanic tunas. Such practices need encouragement through liberalised leasing policies and with funding assistance from the Government.

3.2.15.2 Artificial Reef (AR) is entirely different from Fish Aggregating Device (FAD). FADs are either natural or man-made structures that are used to congregate fish for harvest. The purpose of the artificial reef, however, is to establish a new habitat for fish and other marine organisms to feed and breed. Artificial reef are man-made structures, which are deployed in the sea and targeted to increase coastal productivity in
the long run by providing hard-bottom habitat for growth of sessile organisms and establishing food chains. It increases the chance of post larval settlement of many invertebrates and fish larvae and also the survival of juveniles. The holds, crevices, vertical relief and ledges of the artificial reef structures increase habitat space for marine organisms. AR are generally created to provide habitat or shelter for fish and other marine organisms, serve as a nesting, feeding, breeding, spawning and nursery ground, act as a deterrent to bottom- trawling and other destructive gears, help create fishing grounds and create recreational fishing area. About 45 countries are at present engaged in establishing artificial reefs in their coastal waters. In the past, scrap materials, wooden and bamboo structures, used tyres, broken ships etc were used in the fabrication of artificial reefs. However, due to environmental pollution from some of these material such as tyres and less durability of some other materials such as wooden and bamboo structures many countries now use concrete with steel and high-density polythene materials for the construction of artificial reefs. Artificial reefs too should be strongly encouraged through liberalised leasing policies and financial assistance by the coastal states and with the involvement of fisher community.
Artificial Reefs: M S Swaminathan Research Foundation Experience

In Gulf of Mannar, fish production is declining fast because of over-exploitation and habitat degradation. Bottom trawling, exploitation of berried females and juveniles, coral mining and pollution are the major reasons for the degradation of fish habitats. This resulted in reduced catch/effort ratio. Now fishermen have to put more efforts and inputs to catch the same quantity of fish they caught in the past. As a result, income of the fishermen has reduced substantially. Secondly, catch per unit head of fishers has also decreased drastically. In order to reverse this situation there is need to increase the fishery productivity of the Gulf of Mannar. Fishery productivity of the marine waters can be enhanced by two methods: i) sea ranching and ii) artificial reef. In the present attempt role of artificial reef in increasing fish productivity by providing fish habitat is being demonstrated on an experimental basis. With this background, an artificial reef with four different modules, each 30 in number, was deployed about 14 km offshore from Therespuram village. Fishing community of the Therespuram participates in the development, deployment, monitoring and management of this artificial reef.

Monitoring of the artificial reef using underwater photography showed that most of the modules were covered with a variety of different kinds of seaweeds as well as sessile organisms including soft corals. Apart from this, adults of various species were found taking shelter in the reefs, particularly grouper fish were found in large number within the reef. In addition, local community has also noticed the presence of large shoal juvenile fish of different species in the reef region. All these clearly indicate that this artificial reef is gradually becoming breeding and feeding place of fish, which otherwise indicates that artificial reef can be used as a tool to enhance fishery resources. The Therespuram Artificial Reef Society manages the reef without much problem in collaboration other fisher societies, district administration and Fisheries Department.

Replication of the present artificial reef module has already been started by the Tamil Nadu Fisheries Department. It deployed an artificial reef about 25 km north of Kombuthurai coast near Tuticorin. The Fisheries Development Mission of the Tamil Nadu Fisheries Department provided financial support and MSSRF provided technical expertise in the development of this artificial reef. This reef has three modules, each 35 in numbers. The Gulf of Mannar Biosphere Trust has also allotted funds for the establishment of artificial reef.

3.2.16 Monitoring Changes in Fisheries Environment due to Pollution, Global Warming and Sea Level Rising

Global warming and sea level rise are now a reality. Warming and displacement of ocean currents, flooding, sea erosion, upwellings, changes in fish habitats, impact on breeding and spawning of fish species, changes in biogeochemical cycles, species migration, inundation of coastal lands, loss of wetlands and mangroves, increased salinity of rivers, bays and aquifers, increased nutrients are some of the visible consequences of these changes. Therefore, regular and systematic monitoring of changes in the living resources and the ecosystem due to global warming and their impact on marine fishery should be encouraged.
32.16.2 Environmental concerns, fish health and food safety are integral part of sustainable fisheries. However, the burgeoning population, rapid industrialization, increasing urbanization and intensification of agricultural activities are together causing irreparable damage to the marine fisheries resources. Point and non-point sources of pollution are degrading the environment. It should be however borne in mind that while education place an important role in addressing point pollution, the non-point pollution needs more comprehensive measures. To check this damage, regular investigations are necessary, especially in all the “hot spots” of pollution along the coastline.

3.2.17 Ecosystem-Based Fisheries Management

3.2.17.1 The living aquatic resources are an integral part of their ecosystem and management of the ecosystem is a prerequisite for the well being of fisheries resources. In the Ecosystem-based Fisheries Management (EBFM), fisheries management is not seen in isolation from the wider management of the marine environment and it is integrated with other sectors of marine management. In the EBFM, there could be a close connection between the Integrated Coastal Zone Management (ICZM) programmes and the management options. It is a major conceptual advancement and there are pragmatic ways to begin implementation with interactions of institutions and societies. The following steps are proposed for moving towards EBFM:

- Identification of relevant ecosystems, their boundaries and characteristics;
- Agreement of management objectives for each ecosystem by encompassing wider ecosystem factors and all stakeholders;
- Development of long-term and immediate objectives for each ecosystem;
- Establishment of sustainability indicators such as reference points, targets and limits;
- A decentralized approach enabling management measures to be taken that are appropriate to biologically distinct areas; and
- An effective management capability.

3.2.17.2 In consultation with the stakeholders and other interest groups, short-term and long-term objectives must be agreed upon for each ecosystem. One of the best ways to conserve the marine living resources is to establish networks of fully protected marine reserves of no-fishing zones. The potential biological benefits of Marine Protected Area
(MPA) are increase in spawning stock biomass, healthier fish stocks, strong age/size composition, more yield per recruit, restoration of healthy tropic levels and spill over effects to non-protected areas. All these benefits lead to and enhance the long-term sustainability of the fishery. A carefully planned protocol and implementation of EBFM within a logistic timeframe would be necessary to contribute to the protection of marine biodiversity and fisheries.

3.2.18 Human Resource Development and Welfare Measures

3.2.18.1 To sustain Indian fisheries in the third millennium, the quality, technical skills and management of fisheries manpower will have to improve in consonance with the rapidly changing needs of our society, both nationally and internationally. Human Resource Development (HRD) for raising a cadre of experts at various levels to support research and vindicate a sustained development of the fishery sector is critically important to India. Moreover, to maintain the pace of growth witnessed by the fisheries sector in the recent past, the efforts may have to be probably larger and faster by several times more than made earlier.

3.2.18.2 For the overall good of the sector, there should be an All-India Master Plan for HRD and social security in the fisheries sector. Fishers, women and men have so far relied on their traditional skill both for catching and marketing fish. However, they must benefit from the advancement of technology in both these segments. State Governments must undertake regular programmes for training and capacity building for them in collaboration with ICAR/other institutions and this must form an integral component of the Master Plan for HRD in the fisheries sector. Fish for All training centres on the model of the Krishi Vigyan Kendras (KVKs) should be organized for the capacity building of fisher women and men in the technical aspects of all the steps in the capture/culture to consumption chain. In the HRD at the organised level where formal education in given, there is need for more sector-oriented education and greater linkage between the formally educated and the industry. There is need for the HRD of the labouring sections who are responsible for giving value to the resource by catching, processing and marketing it. Given the continued poverty of the fishing communities and the extreme risk in the occupation, more promotional and protective social security
measures at the national level need to be conceived. There is need for greater emphasis on the role of women in the sector and greater care and attention to the health and welfare of the children in the communities. Measures for ensuring the safety of those fishing at sea need to be given greater priority both during the normal operations and during times of unpredictable weather. Further, the traditional skill of fishers should be preserved and protected and the younger generation should be encouraged to continue fishing through education, training and incentives. A well-planned educational programme at grass roots level should be initiated to implement conservation measures through community-based initiatives. Further, the infrastructure in the 3600 fisher villages must also be upgraded on priority to improve the quality of life of fishers through provision of better road connectivity, appropriate housing, commensurate with the harsh conditions near the coast, clean drinking water, electricity and telephone connections etc. The components and financial resources of the Prime Minister’s Bharat Nirman should be utilised to benefit these fisher villages on priority, considering that the artesenal and traditional fishers represent some of the poorest section of our population and they undertake fairly hazardous work.

**Box - 17**

**Bharat Nirman**

Prime Minister has approved an outlay of Rs. 1,74,000 crores for “Bharat Nirman” which would bring an additional one crore hectare under assured irrigation, connect all villages that have a population of 1000 (or 500 in hilly/tribal areas) with a road, construct 60 lakh additional houses for the poor, provide drinking water to the remaining 74,000 habitations that are uncovered, reach electricity to the remaining 1,25,000 villages and offer electricity connection to 2.3 crores households and give telephone connectivity to the remaining 66,822 villages.

3.2.18.3 **Village Knowledge Centers** should be set up to create awareness and direct access to information on various issues including technology, quality awareness, finance, marketing, processing etc. These centres could provide technology dissemination as well as skill upgradation and could tap the R&D resources provided by the various ICAR institutions. These Village Knowledge Centres could be supported by the State Fisheries Departments and it is proposed to set up one such centre in each State/Union Territory to
give a fillip to fisheries as a source of livelihood and nutrition. 34 such Village Knowledge Centres could be set up at a cost of Rs.50 lakh per centre.

Box - 18

State Institute of Fisheries Technology (Kakinada, Andhra Pradesh)

The State Institute of Fisheries Technology (SIFT) at Kakinada provides an excellent example of state-level institutional support to the fisheries sector. From the original mandate of imparting practical training to marine fishermen in handling mechanised fishing boats with imported gear, SIFT now handles a variety of activities. These activities broadly include training and awareness programmes; induction and refresher courses for officials of the Fisheries Department of the State Government and testing of diseases in fin and shell fishes, antibiotic residue testing, soil and water analysis and testing of other inputs such as feed used in aquaculture.

The SIFT has an attached hostel for outstation trainees, a good library, a state-of-art laboratory for detection of shrimp diseases and testing of antibiotics and other necessary infrastructures. The Institute also generates its own revenue through the fee levied on analysis of animal tissue /soil/water samples and PCR testing of shrimp larvae and adults. SIFT provides a good support to the fisheries sector in the State by meeting the requirements of training, skill upgradation, awareness and other technical advice to the fish farmers and the Department of Fisheries.

3.2.19 Fisheries Legislation

3.2.19.1 For sustainable development of the marine resources the Indian Parliament enacted the Territorial Sea, Continental Shelf, Exclusive Economic Zone and other Maritime Zones Acts in 1976 which led to the establishment of a 200 nautical mile EEZ with effect from January 15, 1997. Since then, India has also enacted a number of other laws and regulations, including the Coast Guard Act, 1978, the Maritime Zones of India (Regulation of Fishing by Foreign Vessels), Act, 1981 and the related Rules of August, 1982. However, we still do not have a legislation to regulate fishing in the Indian EEZ by wholly Indian owned fishing vessels. This aspect needs priority attention of the Government and a comprehensive legislation to regulate the Indian fishing vessels in the EEZ needs to be promulgated. It should prohibit transfer of catch on high seas and provide for the catch to be unloaded only on Indian soil where sufficient spare capacity exists for processing.
3.2.20 Participation in Regional Fisheries Management Bodies and Ratification of International Instruments

3.2.20.1 The 1990s have witnessed many other international agreements and accords relating to the intentions of the international community to achieve sustainable fisheries and to which India has been a party. These agreements represent milestones in international efforts over many years and include Chapter 17 of Agenda 21 of the UN Programme of action which includes programme areas relating to coastal areas and the oceans; the 1992 International Conference on Responsible Fishing (held in Cancun, Mexico) and the 1993 Agreement to promote compliance with International Conservation and Management Measures by fishing vessels on the high seas.

3.2.20.2 India needs to adopt all international fishery and related conventions and agreements. (e.g. Compliance Agreement). In fact, being the largest maritime country in the region we need to set the example. It is also in our strategic interest to do so first. Because of the straddling and migratory nature of valuable stocks like tuna, it is also important to take the lead to strengthen regional fisheries bodies like the Bay of Bengal Programme, which will help to collaborate with the countries in the region, effectively harvest the shared stocks and also widen the use of our national research and technical expertise in the region.

3.2.20.3 The Plans for the Fisheries Sector in the country have so far focused on an integrated approach to optimise production and productivity, augment export of marine products, generate employment, improve socio-economic conditions of the fishermen and fish farmers, conserve aquatic resources and genetic diversity and increase per capita availability and consumption of fish. This focus shows that so far there has been emphasis on development; in other words, more and more exploitation of the resources. However, management, which is often perceived as a response to development, has not received the desired attention. The Code of Conduct for Responsible Fisheries provides an excellent opportunity to integrate management with development and should be implemented with all earnestness.
3.2.21 Separate Department for Fisheries

3.2.21.1 Fisheries, being multidisciplinary in nature, is handled by various Ministries/Departments in both the Central and the State Governments. This has resulted in problems of coordination since various elements of fisheries are handled not only in the DAHDF but also in Department of Ocean Development, Department of Biotechnology, Ministry of Food Processing Industry etc. Many countries smaller than us have separate Departments of Fisheries in view of the importance of the sector. Many States also have separate Departments of Fisheries. Therefore, it is suggested that a separate Department for Fisheries should be set up by the Government of India as a part of the Ministry of Agriculture. This will ensure appropriate focus and thrust to the sector, which has enormous potential of employment generation, food and nutritional security and foreign exchange earnings.

3.2.22 State Road-Maps

3.2.22.1 ICAR has produced state-wise road maps for Fresh Water Aquaculture Development for each State based on its resources and potentiality. DAHDF should hold discussions individually with these States in collaboration with ICAR to identify the road blocks in implementation of these road maps and identify specific inputs needed to implement the road map in a time bound manner.

3.2.22.2 Fisheries offer immense scope for employment generation and production in A&N Islands and Lakshadweep Islands. Fisheries in these islands has not grown adequately due to absence of infrastructure and problems brought about by destruction of coral life by coral lime manufacturing. The potential of these islands has now been recognised by the Central Govt and it is heartening that series of initiatives have been listed in the Comprehensive Marine Fishing Policy, adopted by the government in November 2004. The recommendations are well founded and reasonable and must be implemented in a time bound manner to benefit the economy of these Islands in general and the livelihood of fishers in particular.
3.2.23 Projections

Subject to a reasonable implementation of the provisions of the recent policies/legislation in the fisheries sector and the implementation of the recommendations made in this Chapter, it should be possible to achieve the following levels by the year 2010:

(i) Increase in fish production from the current level of six million tonnes to about eight million tonnes (approximately 3.2 million tonnes from the marine sector and 4.8 million tonnes from the inland sector, mainly from aquaculture and reservoir fisheries).

(ii) Increase in landing and berthing facilities for fishing vessels from the current level of about 25% to about 50%, which would result in reduction of post-harvest losses (from the present level of about 20% to about 10%) and better return on investment for the marine fishermen.

(iii) Perceptible improvements in hygiene and sanitary conditions of landing and berthing facilities.

(iv) Significant improvements in marketing, packaging and transport infrastructure for domestic marketing. This will reduce the role of middlemen and ensure remunerative price for the fishermen.

(v) Productive utilisation of water bodies such as reservoirs, rivers, inland saline/alkaline lands, and waterlogged areas like beels, oxbow lakes and derelict water bodies. (At least 75% of the water spread area to be brought under aquaculture in place of the present level of about 40%).

(vi) Increase in export earnings from fish and shell fish exports from the current level of Rs. 7,000 crore to about Rs. 14,000 crore.

(vii) Creation of additional employment/self-employment opportunities for about one million people.

3.3.0 Conclusion

3.3.1. Effective exploitation of the estimated harvestable resource of 3.934 million tonnes from India’s EEZ would entail extending activities beyond the limits of the area of present exploitation, which is mostly within shore range. Future marine fishing policy needs to be formulated by keeping in mind past experience, the capacity of the present
fishing fleet and the availability of funding for the acquisition of resource-specific vessels. Simultaneously, the emergence of a new world order in global fishery must also be kept in mind. Exclusive access rights have replaced freedom of the seas. This exclusive right is now accompanied by responsibility and sustainable development (Code of Conduct for Responsible Fishing). India must formulate and strictly implement a national Code of Conduct for Responsible Fisheries based on the FAO’s code. UNCED’s Rio Declaration states that the right to fish is conditional and accompanied by the duty to manage and conserve resources for present and future generations. It has therefore to be ensured, that all stakeholders in the marine sector adopt the path of sustainability. Programmes which aim to develop marine fishery must have in-built components of responsible, sustainable and environment-friendly practices.

3.2.24.2 **Additional** requirements of funds for the period till the end of the Eleventh Plan, over and above the existing levels of budgetary funding, for some of the major recommendations of this Chapter are summarised in the Chapter on “Composite Financial Summary”.

**3.3.0 Acknowledgement**

3.3.1 The Commission organised stakeholders’ consultations involving State Govts., scientists, experts, bankers, associations and fishers in Kolkata for inland fisheries, in collaboration with Govt. of West Bengal and in Vizag for marine fisheries in collaboration with BOBP-IGO and Govt. of Andhra Pradesh. Aquaculture Authority of the Govt. of India also organised a consultation in Chennai on the request of NCF, on Brackish Water Aquaculture. The Commission also benefited from the inputs from Consultants/Experts. Their contributions are gratefully acknowledged.
CHAPTER - 4.1
ENHANCING PRODUCTIVITY, PROFITIBILITY, STABILITY AND SUSTAINABILITY

HILL AGRO ECOSYSTEM

4.1.1.0 The State of Hill Agro Ecosystem and Hill Farmers

An Overview of the Strengths, Weaknesses and Opportunities

4.1.1.1 Hills and mountains in India are distributed all over the country with major areas located in Himalayas extending 2,500 km in length and 250 to 400 km in breadth. Himalayas in India are composed of north-western and north-eastern flanks. The Western Ghats, Eastern Ghats, Vindhyas and Deccan Plateau constitute the other major hill agro-ecosystems in the country. These systems cover nearly 50 percent of the total national geographic area and occur in almost all the agro-ecological zones of the country.

4.1.1.2 The perennial presence of snow and glaciers in the Himalayan Region provide vast natural reservoirs of fresh water resources and form the tallest water tower of our planet, dynamically impacting the weather and climate both spatially and temporally-influencing local, regional and global air circulations. Further, the hills and mountains in the country represent extremely diverse agro-ecological settings, providing scope for producing almost any crop, commodity, livestock or fish of the World, whether tropical, sub-tropical, sub-temperate or temperate.

4.1.1.3 The Hills and mountains are the richest repository of biological and agrobiological diversity, and the snow and glacier fields act as reservoirs for terrestrial and aquatic species and snow micro-organisms. Pashmina goats, yak, aromatic rices, landraces of sorghum, veritable fruits and vegetables, multicob maize, saffron, orchids, bamboos, cold water fishes and the like constitute unique germplasm treasures of the hills and mountains. Several rare genes have been used from Himalayas and Western and Eastern Ghats for enriching our major crop species.
4.1.1.4 Besides the major niche resource for hydropower and other productive options, the rich natural resource endowments of the hills and mountains include the bulk of the country’s forest resources/reserves, timber and non-timber forest products, besides possessing rich reservoirs of minerals and medicinal and aromatic plants and tremendous opportunities for various kinds of tourism, including agro-ecotourism.

4.1.1.5 The hills have their weaknesses also. The two most important problems in hill and mountain agro ecosystems are: ecological degradation and high level of poverty. This unholy alliance between poverty and ecological degradation has not been critically studied and analyzed. Economic deprivation and ecological degradation are not unrelated. For integrating the ecological health with economic growth, an understanding of the poverty-ecological degradation nexus is absolutely essential.

4.1.1.6 As regards opportunities, the hills’ unique biological wealth could be converted into economic wealth and can confer livelihood security on a sustainable basis. The bio-treasure provides multiple viable options for diversification. But most of the indigenous variability of different species have not been exploited fully. Niche production of high value crops and commodities, including selected livestock species, cold fishes, high quality seeds, organic farming, production of medicinal and aromatic plants are other opportunities.

4.1.1.7 Yet, most of the hill States have high concentration of hunger and their poverty and agricultural progress has not been upto the mark. Given the inherent agro-ecological and economic interdependence of the hills and plains, the hills–plains divide should not only be halted but also urgently bridged. This paper critically analyses the current situation of hill agriculture and of hill farmers, identifies the issues, challenges and opportunities of the agro-ecosystem and finally suggests pathways to congruently achieve enhanced and sustained productivity, ecological security, economic viability, employment security and social justice.
The Himalayan Agro Ecosystem

4.1.1.8 A highly diverse system: The North West Himalayan Region (NWR), comprising the States of Jammu and Kashmir, Himachal Pradesh and Uttarakhand, covering 331392 sq km, accounts for 10.08 percent and the North East Himalayan Region (NER), comprising eight States, namely, Anunachal Pradesh, Assam, Manipur, Meghalaya, Mizoram, Nagaland, Sikkim and Tripura, covering 262179 sq km, accounts for about 8 percent of the country’s total area (Table 1). Ranging from tarai plains to low, mid and high hills, up to the snowline traversing through valleys, river basins, sub-tropical to temperate, from cold arid to warm and humid, the Himalayan hills have been classified into five diverse agro-ecological zones.

* Figures in brackets are percentage of the country total
Source: Statistical Abstract of India, NBSSLUP
4.1.1.9 **High demographic pressure on the land and other natural resources:** The Himalayan region of India is home to 63.8 million people, 6.2 percent of the country’s population. While the population density in the Himalayas ranged from one-fourth to one-half of the national average in the NWR and NER respectively, the net cropped area per rural person in the NWR, NER and the country as a whole, was 0.11 ha, 0.12 ha, and 0.19 ha, respectively, the wide intra-and inter-State differences notwithstanding *(Table 1).* For instance, the highlands, rising up to the snowline, are sparsely populated and constitute the alpine pastures and grazing lands and the economy is based primarily on livestock, whereas the valleys are densely populated with high cropping intensity.

4.1.1.10 Given the continued high dependence on agriculture for employment and the population increase on the one hand and the decline in net cropped area, the agricultural land availability will further shrink. In order to support relatively larger population per unit area of cultivated land, higher cropping intensities were recorded in the hill and mountainous States, 160 in the NWR and 145 in the NER as compared to the national figure of 134. Forests are the major land use and account for nearly 59 percent of the total area of the Indian Himalayas. However, illegal felling and timber extraction for commercial purpose have caused large-scale deforestation.

4.1.1.11 **Low yields:** Hill agriculture in India has so far remained neglected and the Green Revolution has failed to climb the Himalayan heights. The average cereal and oilseeds yields in the hills are about two-thirds of that of the national average *(Table 2)*, although there are considerable inter State differences. Consequently, self-sufficiency in foodgrains could not be attained so far in the hills. Sugarcane yields in the hills are highly depressed. As regards fruits, vegetables and potato, despite the high agro-ecological congeniality of the hills for these crops, the yields were half to two-thirds of those of the national averages, exception being Tripura which has recorded consistently higher yields for rice, potato, fruits and vegetables as compared with the yields in other hill States as well as with the national average yields. As regards individual fruits and vegetables, the yield gaps between the national averages and NER averages are quite
large, especially for papaya, citrus, banana, apple and onion. Average yields of livestock and fisheries in the hills are also depressed.

*TE: triennium ending

4.1.1.12 Foodgrain crops continue to predominate the agriculture sector despite slight drop in area due to diversification towards horticultural crops: About 75 percent of the gross cropped area of entire Himalayan region, 77.4 percent in the NW and 64.4 percent in the NE, is under staple food grain crops (Table 3). The analysis shows that, the production of food grains has not declined in the Himalayas as much as is often thought of and the per caput production in the hills, especially in the NW, is almost as high as in the rest of the country (Table 4). In the Western Himalayan region, wheat is the main crop and rice, maize, millets, barely and buckwheat, pulses and oil seeds are also widely grown. However, Uttaranchal is unique in the sense that it has more area under millets and pulses. In addition, potatoes and variety of vegetables, off season vegetables, spices, and fruits are also widely grown in the Himalayas. In the North East, rice is the staple food crop occupying about 81% of the cropland area under food crops. In non-rice fields, often diverse mixture of 8 to 10 crops is grown in a mixed farming system by the NE farmers. Crop survey assessments have shown that, although
continuing to be the most preferred crops in certain areas, the area under paddy and maize is declining in the Himalayas as a whole but area under wheat remains unchanged.

Source: CMIE Agriculture; National Horticulture Board, Agricultural Statistics at a Glance

4.1.1.13 The reduction in area under foodgrains is largely because of shift towards cash crops like fruits and vegetables. As seen from Table 3, between 1990-91 and 2003-04, area under fruits in the hill States increased by about 28 percent and under vegetables the increase was 26 percent in the North West and 33 percent in the North East.

4.1.1.14 High livestock density: Indian Himalayas support about 50 million domestic animals (six animals/ha net sown area); cattle (47.5%), goats (15.8%), buffaloes (12.3%) and sheep (10.4%). The livestock density per 100 ha net sown area in the NW Himalayas is 916 and in the NE Himalayas is 499 against 341 for the country as a whole (Table 4). Per caput milk production and availability in the NWR is particularly high, in Jammu & Kashmir the availability is over 300 ml/day. The mountains have a niche for
livestock based livelihoods that one finds in the large areas under rangelands and highland pastures. A large proportion of livestock species is raised under mixed cropping systems. The land holdings are small and livestock substantially supplement the family income and livelihood security. Further, livestock are major source of fuel energy and manure (animal dung and bedding material) or else the number of wood (fuel) headloads carried everyday for heating the pot would increase considerably. An integrated crop-livestock-forest farming system thus holds the key for sustained development of the hill agro-ecosystem.

NSDP= Net State Domestic Product; NSA= Net Sown Area; Source: Statistical Abstract of India; Agricultural Statistics at a Glance; NSSO (1996), CSO, CMIE Agriculture; Livestock Census

4.1.1.15 Over the past one decade, the number of cattle has started declining while the buffalo population is increasing. Similarly, the number of sheeps is declining but the number of goats is increasing. Many reports have been indicating a declining trend in the livestock holding per household but because of increased families overall numbers may not have changed much. The indicators have therefore an important message – the
recognition by hill farmers that maintaining larger livestock holding is no longer profitable. When herd size is reduced there also has been simultaneous shift from local breeds to hybrid cattle and other animals, which induced widespread stall feeding.

4.1.1.16 **Fish potential largely underexploited:** Fish and fisheries, representing more than 100 species and various water body systems such as reservoirs, rivers and lakes and aquaculture involving air breathing fishes are important sources of proteinaceous food, employment and additional income in the hills. However, these resources have remained highly under exploited and there is atleast 4-5 times gap between the potential and the realized yield. For each group of fisheries, specific strategies for enhanced productivity and income should be developed. For instance, the development of open water fisheries involving ranching of hatchery produced seed of Golden Mahseer, Snow trout and Brown trout in the potential stretches of river and the development of lakes of these fishes at mid to high hill altitudes would constitute an important agro-economic activity.

4.1.1.17 A four-fold strategy involving preservation of existing fish stocks, promotion of natural propagation, artificial propagation of selected fish and promotion of fisheries cooperatives would greatly improve development of open water fisheries. Further, integrated fish-cum-livestock farming can yield up to 4-5 tons/ha/year of fish, thus constituting a substantial supplementary food and income. Special areas of interest in hill fisheries should include culture of Exotic trouts, culture of Snow trout and Mahseer, seed production of Mahseer, Snow trout and Rainbow trout, running water culture of common carp, ranching of seed of Mahseer, Snow trout and Exotic trouts in natural waters, Sport fisheries, Ornamental fisheries, high density culture in cages and pens in reservoirs and conservation of important fishes in lakes and rivers. Attention has to be paid to proper seed and feed production, as well as to the efficient management of cubic volumes of water.
Poverty and Undernutrition still high in NER and in Uttaranchal:
Among the 25 million people that inhabit the North Western Himalayas, a large percentage are hill, mountain and highland farming communities. They sustain largely on subsistence farming which they practice on marginal rainfed and some irrigated farmlands occupying 14.5 percent of the total area of the North West Himalayas. Rest of the Himalayan landscape, includes rangelands, pastures, wasteland, the so called bush land - the grazing areas and the forests; all these account for nearly 70 percent of the North West Himalayan area. Another about 15 percent is under permanent snow cover and rocky mountains and serves as perennial source of clean water to the hill people as well as to the rest of the nation.

Agriculture accounts for about 26 percent of NSDP in the NW Region (Table 4). Nearly 60 percent of the people in the NWR are dependent on agriculture for their employment. Average land holding in Himachal Pradesh is about 1.2 ha, followed by 1.0 ha in Uttaranchal and 0.8 ha in Jammu and Kashmir.

The North Eastern Region (NER) has average land holding of 1.92 ha (Table 4), ranging from 0.6 ha in Tripura to 4.82 ha in Nagaland, against the national average of 1.41 ha. The NER has remained underdeveloped and inspite of interventions at the national level, speedy socio-economic development has not taken place. About 65% of the NER is covered with hills and basins, 22% by Brahmaputra valley and 13% by Meghalaya plateau. The Region has a total population of over 39 million, with Assam accounting for 70 percent of the Region’s population. Nearly 58 percent of the total workforce is in agriculture and the sector accounts for 22.2 percent of the NSDP (Table 4), analogous to the corresponding national averages. A large proportion of the population in the NER is tribal and depends on agriculture and land-based activities.

Although per capita income in the hills was only slightly lower than in the rest of the country, there were significant differences between the two regions in poverty and hunger levels. While for the country as a whole, the poverty level dropped from
about 36 percent in 1993 to 26 percent in 1999/2000, in the Jammu and Kashmir and Himachal Pradesh it dropped sharply by about 22 and 21 percentage points, but remained stubbornly high in the NER, dropping only by about 5 percentage points and exceeded 33 percent in 6 of the 8 NER States as also in Uttaranchal. **The level of hunger (% of undernourished populations) followed the poverty pattern (Table 5), in being particularly high in the NE States.**

4.1.1.22 **The potential of agriculture in the NER remains largely unrealized.**

The agricultural production system is predominantly rainfed, mono-cropped at subsistence level. Shifting cultivation (Jhum) is practiced in all the States, except Sikkim, in steep hill slopes with a shifting cycle of 2-3 years. Crop production practices fall under two broad categories viz. (a) settled farming in the plains, valleys and terraced slopes and
(b) shifting cultivation in unterraced hill slopes with “slash & burn” method. Modernization of agriculture has escaped as evidenced from the poor adoption of modern technologies, low consumption of fertilizers and other indicators. In addition to sluggish growth in agriculture, resource degradation and environmental safety issues have also become major concerns of the planners and policy makers. Out of the constraints to agriculture development, the following are unique to the region:

- Primitive agro-economic system in hilly terrain under shifting cultivation leading to land degradation. Limited exploitable water balance in the plains and low ground water potential in the hills have resulted in low level of irrigation. The management of land and water resources, therefore, assumes enormous importance in improving the agricultural economy in the region.

- Inappropriate land tenure (community land for Jhum) and private property rights system in the hilly areas discourage investment and private sector participation in agriculture development. High cost of infrastructure development and relatively low return delays modernization. Such concerns are essentially linked with policies on land reforms, institutional reform, banking and credit and effective governance.

4.1.1.23 In the NER, shifting cultivation or “jhum” accounts for 85 percent of the cultivated area and supports over 2.2 million people, largely tribal communities. The tribal families once food self sufficient, are now barely able to produce enough food for the whole year. The swidden farming is a response to the ecological limitations of humid tropical region and it exhibits a successful human adaptation mechanism to farming in the humid tropics. The swiddeners have developed an agroecosystem that is diverse and is able to respond successfully to the microclimatic diversities and climatic uncertainties.

**Despite advocacy and promotion of Jhum substitution technology packages, the system continues. The ecological prudence of Jhum farming families should be combined with techniques which could help enhance the productivity and sustainability of the system.**
Western Ghat Development Programme

4.1.1.24 The Western Ghat Development Programmes (WGDP) have been in operation from the Fifth Five Year Plan in designated hill areas/ Western Ghat talukas. Under these programmes, Special Central Assistance (SCA) is given to the designated areas in order to supplement the efforts of the State Governments in the development of these ecologically fragile areas. The 161 Ghat talukas - 62 in Maharashtra, 40 in Karnataka, 31 in Kerala, 25 in Tamil Nadu, and 3 in Goa (Table 6), covering an area of 187,144 sq. km., account for 5.7 percent of the country’s total geographical area.

4.1.1.25 The approach and strategy of the programme have evolved through the Plans. During the Fifth Five Year Plan, the emphasis of the programme was on the economic well being of the population in hill areas and exploitation of resources of the hilly region. During the Sixth Plan the emphasis was shifted to eco-development. Apart from the shift in the emphasis from beneficiary oriented schemes to eco-conservation and eco-development, a notable step initiated by the Planning Commission was the involvement of universities and research institutions located in the Western Ghats region in the programme.

4.1.1.26 During the Eight Five Year Plan, the programme focused on involvement of the people and meeting their basic needs through improved management of their land and water resources. Presently, the WGDP operates on the following principles:
• Maintenance of ecological balance,
• Preservation of genetic diversity,
• Restoration of ecological damage caused by human interaction, and
• Creation of awareness among the people about ecological degradation and securing their active participation for the eco-development schemes.

The programmes and activities undertaken over the years are summarised below.

4.1.1.27 Development of cultivable wasteland: One of the main objectives of this scheme is to develop cultivable wastelands in the Western Ghats Region, which are lying unused and when reclaimed will be brought under cultivation of horticultural/plantation crops. The development of land under this sector will be confined to the lower region where scarce wild vegetation exists, without disturbing the ecology in the region, so that immediate benefit could be derived by farming community from land development and plantation of horticultural crops. The following schemes are under implementation: (i) land improvement for soil and water conservation, (ii) assistance for promotion of horticulture crops, (iii) stone wall fencing, (iv) dryland horticulture, and (v) homestead gardens.

4.1.1.28 Conservation activities: Soil conservation aspects on watershed basis receive maximum attention. Maharashtra has initiated the process of implementing the Western Ghat Development Programme on the basis of integrated development of watersheds from 1983-84, which include: (i) land development activities, (ii) water harvesting and erosion control structures, (iii) soil conservation, (iv) water conservation, (v) drainage line treatment, and (vi) plantation.

4.1.1.29 Animal husbandry: The role of the animal husbandry sector in the overall development of the Western Ghats is to complement the eco-conservation and eco-restoration efforts and also to open new avenues of self-employment generation through improved animal husbandry practices. The various programmes which are being undertaken under this sector are: (i) incentives to dairy farmers for renovation of cattle
sheds, (ii) incentives for green fodder cultivation, (iii) supply of fodder mini kits, (iv) animal health cover and breeding, (v) training facilities to dairy farmers, (vi) financial assistance for purchase of milch animals in the watershed area, (vii) opening of artificial insemination centres, (viii) poultry (establishment of backyard poultry), piggery and rabbit development, and (ix) artificial insemination for upgrading cattle and distribution of cross bred bulls and cows.

4.1.1.30 **Fisheries:** The Western Ghats with their innumerable water bodies, small and large, offer good scope for inland fisheries including riverine fishery. Development of fisheries in reservoirs and big and minor tanks and renovation of ponds are some of the important programmes included under fisheries sector. The programmes implemented are: (i) construction of fish ponds, (ii) subsidy to new ponds construction, (iii) development of fisheries in reservoirs, tanks, (iv) renovation of ponds, (v) riverine fishery development, (vi) assistance to fish cooperatives, and (vii) developing infrastructure etc.

4.1.1.31 **Horticulture:** Horticulture assumes greater importance in view of the limited water availability, and also from the viewpoint of economic development and protection of the environment. Under WGDP, the objective of horticulture development activities is to bring the vast stretch of drylands under perennial crops thereby developing the eco-system and upliftment of the socio-economic status of the poor farmers. Various horticulture programmes are being implemented, depending upon the needs and demands in the local areas. The important programmes are: (i) supply of horticultural plants, (ii) training of farmers in horticulture, (iii) establishment of school gardens and community gardens, and (iv) mushroom production and spices project.

4.1.1.32 **Forestry:** Denudation of the thick forests in Western Ghats has been a serious problem. Construction of huge irrigation / hydro-electric projects and expansion of agriculture without commensurate afforestation has adversely affected the ecology in that area. Therefore, the accent of the forestry programmes has been on afforestation in forest lands as well as on private lands. The main programmes under forestry sector are: (i) eco preservation of forests, (ii) heterogeneous forest vegetation by profuse mixed
seedlings, (iii) conservation and protection of degraded forests, (iv) medicinal plant conservation, and (v) wild life management.

4.1.1.33 **Minor irrigation:** The objective of this programme is to ensure proper and regular supply of water for irrigation so as to raise living standards and economic condition of the people by helping to increase their agricultural productivity and production. There is ample scope for developing minor irrigation sources in this region. Constructions of pickups, vented dams etc. can create irrigation potential and consequently bring more area under irrigation. Creation of Openwells, Borewells / Tubewells and Lift Irrigation schemes are the main works.

4.1.1.34 **Infrastructure development:** With a difficult terrain compounded by high rainfall, many places in the Western Ghats become inaccessible due to swollen rivers, land slides, slushy mud roads etc. during the rainy season. The main demand of the population in the area is for all weather roads and foot bridges. The lack of communicational facilities obviously hampers timely attendance of health and educational services. The movement of local produce and other consumer items to these villages is also hampered. Construction of bridges and construction and improvement of rural roads have been the major programmes.

4.1.1.35 **Sericulture:** Sericulture was included as a scheme in the Western Ghats Development Programme during the Sixth Five Year Plan. Limited infrastructure facilities like basic seed farms, industrial silkworm seed grainage, establishment of chawkie rearing centres, pilot extension-cum-training centres and demonstration-cum-training centres have been created. Although still inadequate, these facilities have generated awareness about the Sericulture programme in the rural areas resulting in a larger number of farmers enthusiastically adopting sericulture activities.

4.1.1.36 **Village and Small industries:** In order to generate employment opportunities for the people in the Western Ghats, various schemes are being undertaken through different NGOs. Some of the schemes include employment generation activities
for rural women, establishment of small and micro enterprises in the foot hill regions, dairy, poultry, bee-keeping, curry powder units, vegetable cultivation and tailoring etc.

4.1.1.37 **Non-conventional sources of energy:** This programme was taken up in 1993-94 with a view to promoting non-conventional sources of energy in the Western Ghats as this would to some extent relieve the pressure on forests for fire wood. Devices like solar water heater, solar lanterns, installation of bio-gas plants, wind mills, smokeless choolhas, improved kerosene stove etc. are being promoted under this programme.

**Eastern Ghats Development Programme (EGDP)**

4.1.1.38 The Eastern Ghats region is a part of the Peninsular Plateau comprising the Western Ghats, Eastern Ghats, North Deccan Plateau, South Deccan Plateau and Eastern Plateau. The region is a broken chain of hills that extends from Orissa to Tamil Nadu. The Tamil Nadu part of Eastern Ghats is divided into three physiographic areas: coastal, central and southern spanning three districts in coastal Eastern Ghats, 9 districts in central Eastern Ghats and four districts in southern Eastern Ghats. The major hills in Eastern Ghats are: a) Javadhi hills (Vellore district), b) Pachaimalais (Trichy & Salem districts), c) Kollimalais, Servarayans and Bodamalais (Salem district), d) Kalrayanhills (Salem and Villupuram district), Chitteris and Melagiris (Dharmapuri).

4.1.1.39 The Eastern Ghats cut through by the four major rivers of southern India, the Godavari, Mahanadi, Krishna, and Cauveri. The Ponnaiyar and Palar rivers flow from headwaters on the Kolar Plateau eastward through gaps in the Ghats. The Eastern Ghats is prone to very strong rainfall in the NE monsoon. **Traditional water harvesting structures to conserve the rainwater abound in the Eastern Ghats.** One such example is the Korambu, temporary dam stretching across the mouth of channels, made of brushwood, mud and grass. It is constructed to raise the water level in the canal and to divert the water into field channels for irrigation.
4.1.1.40 The Eastern Ghat is highly significant in terms of its bio-diversity. Extensive field and literature survey of trees in Eastern Ghats yielded 528 tree taxa under 271 genera belonging to 75 families out of the total 2500 species of flowering plants. Medicinal plant diversity is also very high. Out of the total flora of Andhra Pradesh, 1800 are estimated to be medicinal plants, 685 of which are located in certain areas which have been earmarked as Medicinal Plant Conservation Areas. There is also rich diversity in landraces of several food crops. The Eastern Ghat districts of Khammam and West-Godavari in Andhra Pradesh are rich in sorghum diversity, particularly landraces. The Eastern Ghats are rich also in mineral resources, but intensive mining is destroying large parts of the agricultural land. Various economic activities should be balanced to ensure sustainabilities.

4.1.1.41 Because the hills and the surrounding plains are densely populated, accessibility to the forests is rather easy. The forests in the Eastern Ghats are the most affected, compared to the Western Ghats and Himalayas, as they are experiencing heavy demographic pressure. A study featuring the forest degradation in Kolli hills which is a part of the Eastern Ghats revealed an observed loss of about 25 ha in dry evergreen forest; and about 35 and 1306 ha loss was observed in the semi-evergreen and dry deciduous forests, respectively. About 69% of the present forest area is under low risk category, 25% is under medium risk category and about 2% (581 ha) is under the high-risk category. Severe fuel-wood extraction, illegal felling and intensive grazing are the main reasons for this change.

4.1.1.42 An ethnobotanical study was carried out during 1995-2001 in the Eastern Ghats region of Andhra Pradesh covering the districts of Chittoor, Cuddapah, East and West Godavari, Guntur, Khammam, Krishna, Kurnool and Visakhapatnam. The study revealed the tribal populations of Chenchus, Erukalas, Koyas, Konda Reddis, Lambadas (Sugalis), Naikpods, Nukadoras, Valmikis and Yanadis. The tribal communities are associated with cultivation and use of several endemic species and have discovered the ethnic uses of 9 epiphytic and 11 terrestrial orchids. A total of 29 accessions of local landraces of Sorghum were collected most of which was used for food.
conserving the useful flora can be done only with the close cooperation of these tribal communities.

The Deccan Plateau Development Programme (DPDP)

4.1.1.43 Deccan Plateau covering 644910 sq. km, about 20 percent of the country’s total area, stretches across Andhra Pradesh, Karnataka, Southern Maharashtra, Southern MP and TN. About 70 per cent of the population work in agriculture. Nearly half of these are small farmers cultivating as little as two acres. The other half work as hired agricultural labourers for larger farmers. Poor soils and low and erratic rainfall have resulted in poor productivity in the region.

4.1.1.44 In the Deccan plateau, the areas that fall in the rain shadow regions of both the Western and the Eastern Ghats, ensuring adequate availability and quality of water is a major priority. Rainfall is lesser than many other areas of the country, coming to as low as 500mm a year; its pattern fluctuates widely and its spread is also very erratic.

4.1.1.45 However, to survive the erratic water availability, the traditional communities have developed a network of water harvesting structures and intricate irrigation networks. For instance, the Kohlis, who are a small group of cultivators residing in the district of Bhandara, Maharashtra, built some 43,381 water tanks over several centuries. which formed the backbone of successful irrigation in the area. So is the community managed Phad Irrigation system that existed in Maharashtra.

4.1.1.46 There is also considerable diversity in crops and crop sequences where traditional crops such as millets and cumbu met the nutritional as well as cultural requirements of the local communities. However, they are being replaced steadily by cash crops to meet the market requirements. Replacement of cultures and traditions has replaced local and adapted agro biodiversity as well.
4.11.47 The following development programmes deserve high priority both for Eastern Ghats and Deccan Plateau:

a) **Judicious water management of surface water and groundwater and re-vitalisation of traditional water harvesting structures and water saving measures have to be identified and upscaled.** Irrigation measures to supplement rainfall are very important for crop production stability. Watershed development needs to be more holistic and should integrate should biodiversity conservation. Floods and droughts occur frequently in the Eastern Ghats, which should be managed with adequate knowledge through early warning systems and flood mitigation measures.

b) **Soil conservation** should be followed encompassing (i) adequate soil cover to prevent exposure to direct sun, rain and wind, (ii) mixed farming, (iii) rainwater conservation and (iv) adequate regenerative capacity of the soil so that it could manure itself.

c) Instead of focusing only on hydroelectric power, **alternate measures of energy development** – wind, sunlight, need to be identified and upscaled. The development and use of **biofuels** generating crops as part of wasteland development is highly recommended.

d) The shift away from crops such as sorghum and millets which are ideal for the dry parts of the Deccan and which used to be a part of the consumption pattern of the residing population needs to be rectified. The increased emphasis on rice and wheat (brought about by the wide scale availability through the PDS) must be corrected by **diversifying the PDS through the inclusion of locally-produced grains.** Adequate market access is essential to revitalize crops such as the millets which are disappearing from the food basket.
e) **Agro-biodiversity exploration, conservation and enhancement are a top priority** both in the Deccan and the Eastern Ghats. This has to be set in the context of local cultures and traditions.

f) **Involve the local people and local governance mechanisms**, particularly the Panchayats, for conservation through community action by the formation of cooperatives and groups and for realization of the Farmers’ Rights provisions.

### 4.1.2.0 Horticulture-led Transformation of Hill Agriculture

4.1.2.1 As seen from **Table 3**, between 1990-91 and 2003-04, percentage areas under fruits and vegetables in the NW Himalayas increased from 12.5 to 15.9 and from 4.01 to 5.06, respectively. In the NE Himalayas, the corresponding area percentage increases for fruits were from 3.8 to 4.8 and for vegetables from 6.12 to 8.14. These increases in relative terms were much higher in the hills than in the plains. As seen from **Table 4**, per caput production of fruits in the Himalayas is thus now about 60 percent higher than that in the rest of the country. Likewise, per caput vegetable production in the NER is about 25 percent higher than that in the country as a whole.

4.1.2.2 **The entire Himalayan range is a favourable agro-ecosystem for growing a wide range of fruits, vegetables, medicinal and aromatic plants and other cash crops.** Small areas with their own micro climatic conditions provide suitable sites for growing particular crops, such as apples, citrus fruits, walnuts, plums, peaches, bananas, mangoes and pineapples; vegetables such as tomatoes, radish, potatoes, cabbage, cauliflower and several local and introduced temperate vegetables, other cash crops like ginger, chillies, cardamom and saffron; and flowers such as orchids, gladioli, marigolds and chrysanthemums. The fruits and vegetables cover around 16% of the crop land. **The present trends towards rapid expansion of horticultural crops will have positive implications for improving food and economic security of hill farmers.**
4.1.2.3 In some of the States, in Himachal Pradesh for instance, apple accounts for 76 percent of the State’s total fruit production, horticulture will lead the future agricultural and economic growth. The fruit-based production system has helped alleviate poverty of many hill farmers of Himachal. Over 86% of the population is now literate and there is almost 100% literacy below 14 years. From the viewpoint of employment and income generation, fruit and vegetable farming are high quality options for hill farmers. The high quality of production options is also evident from the backward and forward linkages generated by them. Fruit crops farming in Himachal has helped convert the non-viable subsistent farming into viable farming through harnessing of appropriate niche potentials of marginal mountain lands. However, the overdependence on apple may not be desirable.

4.1.2.4 With the diversification of farming in the hills, however, many second generation issues of unsustainability, ecological compatibility and social, gender, ethnicity and equity sensitivity are emerging. The landmark study “Warning signals from the apple valleys”, analyses one such problem of pollination failures making a dent on productivity of apples in Himachal. But, this has also brightened the prospect of installing honeybee hives in and around the orchards, not only increasing pollination and fruit set in apples, but also generating substantial additional income, employment and nutrition through enhanced honey production thus converting challenges into opportunities. In fact, honey production in Himachal Pradesh has increased to about 1,200 tonnes annually and it has become an important source of income and employment also in Jammu & Kashmir and in Uttarakhand.

4.1.2.5 Among plantation crops, the development of smallholder tea cultivation in Assam spread over 40 thousand ha is an emerging phenomenon in the NE region, which has potential for converting to ‘Organic Tea’. Large cardamom farming as an understorey crop in hill slopes of Sikkim is a unique traditional production system conferring high ecological stability. As a high value cash crop in Sikkim, it generates employment for 80-100 days per ha (Box 1). Popularisation of seabuckthorn in cold arid Himalayas and in China is yet another success story (Box 2). These success stories are quite replicable and
detailed location-specific plans and activities for their replication, involving various stakeholders, should be formulated and implemented.

4.1.2.6 Loose skin mandarin orange is a unique high value crop in the NER. Broadly named as ‘Khasi orange’, it grows well both in Assam valley as well as in the hill slopes. The fruit quality is excellent, and unlike Nagpur orange which is entirely on budded plants, the plantations in the NER are raised from seedlings only. Due to neglect, the orange trees are suffering from malnutrition and disease and insect infestations, resulting to severe decline. Still in certain pockets trees are highly productive, and if due care is taken, orange industry can revive back with a real boost to the agricultural economy of the region. Under the Horticulture Technology Mission, considerable expansion of passion fruit area (3885 ha) has taken place, particularly in Mizoram, Sikkim and Nagaland. Processed passion fruit has a good export market and a few processing units have also been established.

**Box 1**

**Forest Floor Farming of Cardamom in the forests of Sikkim**

The subsistence dry land farming on sloping crop lands of north Sikkim should be presenting the poverty cum resource degradation scenario for farmers. However, ethnic mountain farming communities of Sikkim had chosen a wild high value spice – cardamom for barter and cash income source. The farmers started farming it under the forest floor like any perennial crop. For decades now, cardmom is their high value cash crop grown under the shade of natural forests as well as under alder afforestation.

Almost 75% farmers of north Sikkim have replaced the food grain agriculture on their farmlands with cardamom and alder tree plantations. Cardamom-alder forestry plantation provided permanent green cover to thousands of hectares i.e. 23% of farmland. The contribution of cardamom farming to livelihoods ranges between 40-88%. Four key factors which make cardamom farming on marginal sloping lands useful are:

- It is ecologically adapted to farming on sloping lands and forestry system and the plants maintain permanent green cover on forest floor.
- Cardamom farming ensures ecological stability to fragile mountain slopes by requiring farmers to maintain a good forest cover of nitrogen fixing alder trees.
- Cardamom is farmer domesticated, low volume-high value cash crop and it generates employment for minimum of 80-100 days per hectare.
- Globally almost 90% of cardamom is produced in Sikkim and its neighbouring valleys of Nepal and Bhutan alone, therefore, the region is the
4.1.2.7 Apple was introduced in rain shadow belts of Arunachal Pradesh, mainly in Kameng district where annual rainfall is around 900 mm. It is reported that about 5000 ha was brought under apple and quality of fruits was excellent. Unfortunately, there was no after care and science-based back stopping, resulting in poor performance. Under high rainfall condition even at 6000 to 7000 ft altitude of NEH (upper Shillong in Meghalaya, Phutsero of Nagaland etc) apple was not a successful crop and therefore the niche found in Arunachal Pradesh needs to be nurtured to meet the demand of local market. Apple industry in Bhutan with a new set of varieties is showing promise. Snow clad dry hills of Sikkim are also suitable for apple production.

Box 2

**Forest as an orchard**

Seabuckthorn provided a breakthrough in combining strategic desert conservation needs of China with local economic needs in north and northwest China. Seabuckthorn plantations and R &D in post harvest processing of wild fruit into variety of valuable products including medicines, have made marvellous impact on both the household and regional economy. China has now well managed seabuckthorn forests covering more than one million hectares and by the end of 2004, seabuckthorn agroenterprise was a multi billion agroenterprise in China.

Seabuckthorn success story is one of the outstanding examples of development approaches for hills which combine horticulture and forestry to promote an economically and ecologically productive hill farm economy. A forest of wild seabuckthorn bushes represents characteristics of a good forest on the sloping lands and river valleys, as well as economically productive features of a fruit orchard. Local farmers of the areas have strong economic interest in maintaining the seabuckthorn forests and government institutions have long term strategic (ecological) interests in promoting it.

LEH BERRY brand name in India, is a result of replication of the Chinese success story. Ten years of efforts of international agencies and encouraging private investment has led to the establishment of RS 100 crore LEH BERRY brand agro-enterprise in India since the year 2001, benefiting farmers of Ladakh (Nubra valley) in J&K and tribal districts of Himachal Pradesh.
4.1.2.8 It is very essential to plan for development of those crops only which are easy to grow and are well adapted in the prevailing agro-climate. An analysis of productivity of major fruit crops in different States and other comparative advantages in terms of market accessibility and demand should be taken as the basis/criteria while formulating the area expansion programmes. For example, crops like banana, pineapple and orange are grown in all the North East States. But the productivity of these crops vary vastly in different areas. Perusal of yield data and other parameters like net income per ha, market demand, peak season of arrivals and price trend in major markets should be kept in mind to regulate the production-marketing chain.

4.1.2.9 Ginger is already a well established cash crop in Meghalaya and Mizoram and the crop received developmental support to possible extent. Large-scale seed production of improved varieties like Nadia in Meghalaya, and marketing support in Mizoram encouraged ginger cultivation. There is still a good scope for improving the productivity in ginger and some processing support (dehydrated ginger of low fibre containing variety) may boost the crop further. Ginger should be encouraged in Assam and Arunachal Pradesh, where productivity is quite good and ample scope for its improvement remains. Sikkim has come up well with ginger production in more recent years. APEDA report shows that ginger export from NER has already started and during 2001-02 about 1640 mt were exported. Export-led growth of ginger deserves focused joint attention of the concerned State Governments, SPS and quality assurance authorities, private sector and NABARD and other banking institutions to particularly promote WSHG activities.

4.1.2.10 Out of all vegetables, potato is the most important one. Potato yield is quite high in Tripura and the State has already achieved the distinction of commercially producing TPS. In the plains, potato is harvested in winter months (Dec.-Jan.), but in the hills of Meghalaya harvesting takes place in the months of July-September. Price trend in Kolkata market clearly shows that although maximum arrival takes place in November-December, maximum price is realized during the period of June to November. The yield of potato in Assam is about 8 t/ha, against about 26 t/ha in West Bengal. But the advantage of off-season harvest needs to be exploited to the maximum extent and potato
cultivation should be encouraged in mid-high hills of NER. A good number of improved varieties and suitable management practices have already been worked out by the CPRI Station in Meghalaya and NEC support has been provided for seed multiplication locally. Potato is an important cash crop in the hill districts. It shows positive growth throughout the period and the yield has doubled during the last 30 years and the trend needs to be accelerated through improved extension, irrigation expansion and input and market supports.

4.1.2.11 In case of vegetable crops, improved production should be possible much faster. Unlike in the case of fruits, in vegetables research information and farmers’ rich experiences are available in case of most of the vegetable crops. Intensive vegetable cultivation in Nowgang district of Assam, growing of climbing beans in mixed stand with maize in hills, raising locally good quality seeds of radish and cauliflower, are some of the examples which show farmers’ interest and skill in vegetable cultivation in the hills. New improved varieties and hybrids should cover larger areas in flat and valley lands in the hills. Vegetable production has improved considerably Horticulture Technology Mission claims to have brought 9000 ha additional area under different vegetable crops, especially in paddy fallows as the second crop.

4.1.2.12 Vegetable farming has particularly helped small and marginal hill farmers come out of poverty trap. The often quoted off season vegetable farming in the hills signifies intensive use of small landholdings of hill farmers using their family labour most productively (generating better employment for the family on farm). It has already transformed livelihoods of millions of families across the Himalayas. The concerns of such families today is sustainability of the option and not the alternative. Indeed, vegetable farming is most promising option for small farming families, but it is ecologically highly unsustainable; the cost of cultivation keeps rising year after year. The need for excessive use of fertilizers and pesticides is a continuing concern both for the farmers as well as the consumers. The private companies and market forces have replaced the role of research and technology institutions as sources of new varieties and inputs for vegetable farming. Therefore, the public institutions, ICAR system including the agriculture universities need to reform and strengthen themselves for new roles as
technological innovators and back up supporters for hill resources management and profitability of hill farmers through a participatory mode. The KVKs and ATMAs can play an important role in this direction by undertaking location-specific activities rather than dumping on the hill farmers the technologies developed in distant plains of India and elsewhere.

4.1.2.13 In flowers, orchids, particularly the temperate orchid Cymbidium, is the specialty of the NE region. Although sporadic attempts have been made to commercialise orchid cultivation in Sikkim, Darjeeling district of West Bengal and Arunachal Pradesh with Cymbidium, full potentiality is yet to be exploited. Of late, big units with protected cultivation structures are coming up mainly in Sikkim. M/s India Carbon Ltd., Guwahati, took to commercial production of tropical orchids, but only with limited success. Cluster of small farmers / SHGs may approach M/s Indian Carbon Ltd., Guwahati, M/s Nagami Nursery, Dimapur, NRC for Orchids, Pakyong, Sikkim, and the like, for sourcing quality planting materials and for possible tie up for marketing arrangement, including appropriate contract farming arrangements, as common in Thailand and other South East Asian countries.

4.1.2.14 Anthurium, another crop of cut flower value, is also coming up well in some of the hill States. Commercial scale production from Mizoram is reported and some marketing arrangements have also been established. Private initiatives to develop contract growing for orchids and Anthurium, organizing training on floriculture, setting up tissue culture hardening facility and others are in the pipeline. The Government of Assam has targeted Kamrup district as a floriculture district of Assam. Among Medicinal and Aromatic Plants, Citronella grass cultivation for aromatic oil was extended to a reasonably large area, including in the unutilized lands of tea gardens. RRL, Jorhat of the CSIR has identified suitable strains and assisted in establishing distillation units. Due to good rainfall and rich soil, the vegetative growth of aromatic grasses is luxurious, particularly in the valley lands. But, the potential remains highly underexploited and the necessary synergistic push of the stakeholders is missing.
4.1.2.15 Patchouli (*Pogostemon cablin*) has been identified as a suitable essential oil bearing aromatic plant with immense export potential. Patchouli oil production could be a rural based, labour intensive, low cost agro based cottage industry in the NER. Due to active support of NEDFi (North Eastern Development Finance Corporation Ltd) for production of patchouli oil on commercial basis under a buy back guarantee, already about 1800 acres have been covered under Patchouli. Patchouli cultivation is being promoted also in the plains of Assam, while another essential oil bearing ‘Geranium’ is considered for the hills. **NEDFi micro-finance scheme is aiming to support NGOs / SHGs for promotion of medicinal and aromatic plants, which definitely enjoy a niche in the NER.**

4.1.3.0 Issues and Challenges of Hill Agriculture and Concerns of Hill Farmers

4.1.3.1 **Lack of fact-based rational understanding and of knowledge-led development approaches have been the main reasons for the poor state of hill agriculture and deprivation of the hill people.** Hill area development in India has been based on the perceptions of *Land Degradation Theory* that was so widely dramatized in 1970s through the book *“the Himalayan Dilemma: Land Degradation and Human Poverty”* by Ives and Messerli. The vicious cycle of poverty-land degradation-food insecurity-poverty was coined during that period. It blamed hill farmers for the forest denudation and land degradation problems leading to downstream floods, siltation and desert like situation. It predicted dooms day for the Himalayan farmers by the end of 2000. The fundamentals of the theory were that Himalayan farmers are causing large scale soil erosion and land degradation in the Himalayas and their farming cultures are the root cause of floods in Bangladesh, large scale forest denudation and land degradation and siltation of dams, rivers and even the Bay of Bengal. The theory linked their poor livelihoods to all these evil processes. **Without verification, everyone accepted the theory.** More data was generated by other agencies in further support of these observations. The aid agencies, both multilateral and bilateral, the World Bank and Asian Development Bank and others, made countries of the region think and act accordingly. Several government programmes such as stricter forest policing and forest laws for
conservation with little concern for livelihood security of people in and around forests, were outcome of this process. The muddiness of the current debate on the rights of the tribal people could, to a certain extent, be ascribed to the Ives-Messerli theory.

4.1.3.2 After about four decades, we have a situation where the hill farmers, the villains of the theory and real victims of the counter measures, are in crisis. New evidence is now available to explain that the Himalayan degradation theory was a mis-judgement of nature’s processes and that Himalayan farmers have suffered over the decades because of the international and national initiatives on pro conservation policies and investments. The world over unrest in the mountains, that emerged during this period, has been attributed to policies and interventions made during this period, which denied or restricted rights and access of hill people to their livelihood resources, be it the tribals of NE India, the tribals of northern Thailand, Myanmar, Bangladesh or the Andean Indians of Latin America, or be it the sheeps of the Valley of Flowers in India. The new findings observe that, unfortunately, today the Governments and institutions in the affected countries are not ready to listen to the new findings. There is so much of vested interest within these national systems (conservation lobby) that new findings are being fiercely resisted and dubbed wrong (Box 3).

4.1.3.3 These findings have great implications for shaping the course of events for the hill farmers. It calls for unloading the soil erosion and degradation loaded mind sets of researchers and development thinkers and seeks revisit of the whole issue in the light of new knowledge and information to verify the situation and make necessary changes at whatever level they will be needed - policy, development programmes, research and even academia. The new findings highlight the need for pro hill people policies rather than putting priority on conservation of resources over people. New mantra is – “Given the opportunity and supportive conditions hill people are masters in conserving resources.” Governments only need to create an enabling environment, in place of whole range of restrictive regimes which have alienated hill farmers from their own environment making them refugees in their own surroundings.

4.1.3.4 Another major knowledge gap exists for reliable estimates of total forest area and areas under different forest categories. The geographic areas of hill States have
been calculated long ago using available means and these tools had limitation of not being able to calculate the area under verticality of hills and mountains. This means that official geographic area of all hill States is as if they are plain, and it does not include area created due to verticality factor. The new tools i.e. GIS based digital elevation models and other tools now help us calculate the area correctly. For example, the official area of Himachal Pradesh is 55,000 sq.km but when new tools were used the actual area turned out to be 88,000 sq.km. A difference of 33,000 sq km is huge indeed. This extra land holds the key to solving many problems of hill farmers. This extra land is not crop land, because crop land is measured and recorded in the revenue records. Then it may be the forest land, and if that is true, it should facilitate major policy decisions about need for land use adjustments.

4.1.3.5 **Besides the main issue discussed above, hill agriculture has some inherent challenges of remoteness and inaccessibility, lack of connectivity of production areas with all weather link roads, marginality, and fragility in terms of moisture stress, depleting soil fertility and the poor soil conditions and a short growing season. Added to these are socio-economic constraints such as small and fragmented holdings, poor productivity, labour shortages, poor post production management, poor marketing and networks (lack of market development) and lack of entrepreneurship. All these have led to underutilization of resource bases in the hills and the limited generation of surpluses and low returns to the farmers.**

4.1.3.6 **With few exceptions, constraints to improved agricultural production in the Himalayas include poor management practices, inferior quality and inadequate quantity of planting material, seeds, and other inputs, little access to extension services and marketing. Crop damage due to unpredictable weather as well as from wild and astray animals is a major deterrent. Across the Himalayan region, farmers face problems in accessing market information, post harvest processing and value adding skills and opportunities. Because of the lack of regular markets and reliable marketing and due to the high marketing costs, hill farmers in many areas are finding it too risky to diversify into more lucrative high value crops.**
4.1.3.7 Shortage of fodder and feed is rampant in the hills. “Livestock fodder problem is more acute than human food problem in the hills”. The rangelands and grasslands are operating at one fourth of their productive potential. Most of the fodder and grazing areas have been infested by non-palatable invasive species, such as lantana, eupatorium and congress grass. As an estimate, about 40-60% shortage of fodder is being faced by the Himalayan farmers.
Box 3

Forests and Floods  
*Drowning in fiction or thriving on facts?*

Flood processes in Asia are highly complex. Only integrated approaches take this complexity sufficiently into account and lead to adaptive and effective flood management. An improved approach to watershed and floodplain management integrates land management in the uplands with land-use planning, engineering solutions, flood preparedness and emergency management in the lowlands. This requires good understanding of all the physical processes involved, as well as the social behaviour and culture of local residents. Furthermore, this approach should draw upon the best available scientific knowledge about the environmental, social and economic impacts of floods and the environmental, social and economic effects of interventions.

The myths and misperceptions about the causes of flooding that have misguided decision-makers, planners and managers alike need to be replaced by rational understanding based on facts. Too many local, national and international agencies have used ‘conventional wisdom’ and unsupported claims to advance their own institutional interests and because it has been politically advantageous to channel aid funds to upland reforestation and conservation projects. The media has unfortunately perpetuated many of the myths regarding forests and floods out of a well-intentioned, but ill-informed, desire to protect the environment, especially the forests of upper watersheds.

It should be clear that large-scale reforestation programmes, the adoption of soil and water conservation technologies in agriculture, logging bans and the resettlement of upland people to lowland areas will not significantly reduce the incidence or severity of catastrophic floods. Positive environmental impacts from these interventions will be of a local nature, while the negative social and economic impacts are likely to be more widespread.

Importantly, the habit of blaming upland inhabitants for catastrophic floods of whole river basins must be abandoned. Instead, practical solutions are needed to redress watershed degradation caused by unsustainable land-management practices, including poor logging practices and inappropriate infrastructure development. While refraining from exaggerating the negative impacts that mountain people have on the environment, we should also not overstate the positive impacts of their participation in watershed management programmes, as is happening with some recent attempts to develop markets for the environmental services that forests may provide. Moreover, policy-makers and development agencies have a moral and ethical responsibility to ensure that regulatory and project approaches are based on the best available scientific knowledge and do not unnecessarily place upland communities at risk of further impoverishment.

While the ability of forests to prevent catastrophic floods is limited, watershed management should definitely not be abandoned. Forests provide a variety of environmental services, which need to be protected and nurtured for the benefit of today’s and tomorrow’s upland and lowland populations. Watershed management needs to consider the needs and interests of local populations, but should also account for the needs of the wider society. The most effective approaches to reducing damage caused by catastrophic floods require a strong focus on downstream areas and flood plains. People in these areas need to ‘learn to live with rivers’, as the UK Institution of Civil Engineers entitled its 2001 report on flood mitigation measures. At the same time, politicians and policymakers need to abandon their belief in quick fixes for flood-related problems. While the high costs of floods in the lowlands of Asia are evident, it is important that the beneficial aspects of floods are also acknowledged. It is only by promoting and supporting comprehensive integrated watershed and floodplain management that the needs and aspirations of all residents — uplanders and lowlanders — can be adequately addressed.

FAO, 2005
4.1.3.8 Livelihoods of majority of the population in the Himalayan region revolve around agriculture, land being the nucleus of all socio-economic activities. For majority of the small and marginal farmers, their wealth and poverty is associated with the ownership of the size of land holdings. The great majority of the farming households are marginal (below 0.5 ha) and small (0.5 to 1.0 ha) landholders. The situation is particularly unsatisfactory in the North West and in Tripura. For instance, by 2010, nearly 90 percent of the holdings in Himachal Pradesh, and over 96 percent in Jammu and Kashmir will be less than 2.0 ha in size. Sometimes, land ceiling laws prohibit bigger holdings, which may need to be reviewed while promoting contract farming.

4.1.3.9 Shrinking cropland holdings is a key concern for managing food and livelihoods. Rural development efforts across the Himalayan region face a serious challenge of finding a solution to this problem. The per capita available cropland in hilly areas across Indian Himalayan states is already too little to sustain livelihoods. The consequences of this situation to sustaining livelihoods and management of land resources are serious indeed. The Himalayan cropland which is about 4.3 percent of the country’s cropland has to support livelihoods of disproportionately large number of mountain people, who account for 6.2 percent of the nation’s population. Moreover, the hill and mountain cropland is divided into a range of flat and sloping land types. While 37% of the cropland is sloping land of various degrees, the Himalayan farmers are cropping sloping lands even beyond 25 and 30 degrees. Down in the valleys, new human settlements, urbanisation, industrialisation and government infrastructure development activities, all are competing for converting the valley crop land into non farm use. For instance, in Himachal Pradesh, net cropped area decreased from 5.82 lakh ha in 1990-91 to 5.49 lakh ha in 2001-02.

4.1.3.10 Implications of cropland scarcity in hills are manifold in the form of indicators of unsustainability of hill agriculture in respect of land resources, production and livelihood (Table 7). The unsustainability indicators are in fact hidden responses of farmers to the lack of access to cropland of adequate size and quality. The state of croplands in the hill region and its impact on the food insecurity and continuing poverty paint a grim picture for sustainable hill agriculture. The key issues that emerge are,
shrinking size of land holdings, erosion from sloping farmlands and decline in soil fertility and, above all, strengthening of the nexus cycle of inadequate food production-food insecurity-poverty-resource degradation. It highlights the fact that unless solution is found to cropland scarcity, agriculture as a source of sustenance for the small and marginal farmers may lose its significance.

4.1.3.11 All across the Himalayas, declining size of landholdings has seen virtual invasion of farming communities on the non-farm CPR land, wasteland, rangeland, forest areas etc. for conversion into cropland. Many areas, particularly Uttaranchal, are witnessing increasing out-migration of males. It has created a unique situation in which sizable percentage of women are today heading farming households and economy of these households is at best known as money order economy. Thus, the already leading role of women in hill agriculture is further enhanced. Further, the outmigration of males beyond a certain proportion may be detrimental to hill agricultural economy in the long run and should be checked by creating in situ employment opportunities for them.

4.1.3.12 Several hill States present success stories of agricultural diversification through fruit and vegetable farming which have helped improve the livelihoods of small and marginal farmers. The diversification is, however, already facing second generation problems and the challenge of sustaining and widening benefits of hill agricultural diversification is beset with range of new problems such as:

- Large proportion of marginal farmers are yet to benefit from agricultural diversification
- Cash crop farming is facing pricing, marketing and sustainability problems
- New generation of farmers, the educated unemployed youths, are keen to explore entrepreneurship opportunities, but not with much success. (Millions of educated unemployed youth across the Himalayan States, mostly from the farming families are waiting for jobs. Even though many of these educated unemployed youth have acquired traditional knowledge of farming from their families, they need to be equipped with necessary knowledge and skill in farming, entrepreneurship and agribusiness).
• Unexplored comparative advantages of hill agriculture
• Constrained livelihoods because of biological degradation of support lands – the waste lands
• The hill and mountain farmers lack appreciation of climate change, and
• Weak mountain agricultural research and extension support services.

Table 7: Indicators of unsustainability of hill farming and livelihoods
(Time Frame 1954-1991 = 37 Years Approx.)

Note: A positive sign (+) means increase and negative sign (-) means decline/ decrease
4.1.4.0 Opportunities in Hill Agriculture: Transforming the Vast Marginal Hill Lands into the Lands of Opportunities

4.1.4.1 Hill agriculture and the Himalayan areas have specific advantages that can be harnessed to good effect, in particular the wide diversity and the presence of niches particularly suited to certain crops e.g. apples in Himachal and saffron in Soppore Valley of Kashmir, pashmina goats and yak in the highlands of Ladakh or mithun in Arunachal Pradesh. It offers hope to develop these comparative advantages, promote investment in such niche areas as part of the efforts to improve farm economy in sustainable ways.

4.1.4.2 Apple farming on marginal farmlands in Himachal Pradesh, cardamom plantations in the forests as well as conversion of sloping farmlands into forests for planting cardamom, and afforestation of barren land with seabuckthorn in Ladakh and China, constitute the technological options which reflect better understanding of niche perspective — the real niches consider use of local biodiversity as priority. In these examples, marginal land was adopted as a given condition and agricultural development options were searched accordingly. The commonalities among these examples are productive use of marginal farmlands, support for land, soil and water management and harnessing of specific niches.

4.1.4.3 The three examples convey a message that marginal lands are not constraints to productivity if appropriate technological choices are made. Marginal lands have specific niches(comparative advantages). A proper understanding of the niches can provide clue to the potentials of marginal lands under given agro ecological environment. The three production systems use perennial plantations of different types with equal advantage - be it modern varieties of apples or a farmer domesticated perennial spice cardamom or a wild thorny shrub - seabuckthorn. All the three production systems aim at combining economic sustainability with ecological stability of the landscape and local environment.

4.1.4.4 Cardamom farming highlights two points, one is that local biodiversity can be a good source of niche based crops for marginal lands. The perspective behind the marginal
land crops is that these are the plant resources adapted to edaphic and climatic conditions of marginal lands. These may not be the crops coming from experimental stations of research institutions but local plants whose economic potentials have been determined by the market or industry. Seabuckthorn story provides insights to technological scope for combining soil and water conservation efforts on marginal and fragile land with food security and poverty alleviation. Seabuckthorn case is a unique example, which explains that forestry systems can be designed in such a way that while serving the purpose of good forests they can also provide benefits of horticulture plantation to local people. Seabuckthorn initiative also explains how forests can be made to serve as fruit tree farm in terms of offering livelihood opportunities.

4.1.4.5 The experiences described above add a new dimension to the thinking process about linking marginal land management to improving livelihoods. The trends unfolded by these case examples define a role for biodiversity/agro biodiversity in enhancing use value of marginal lands for sustainable hill development strategies. The core message of the three technological successes is that a change in the development thinking from “considering marginal hill lands as constraints to livelihood opportunities and poverty alleviation to that of lands of opportunities” is bound to synergise ecological and economic gains in hill agriculture leading to sustained livelihood security of the hill people.

4.1.4.6 A few other promising trends have emerged in recent years which should be consolidated to achieve the ultimate goal of happy hill farming families. For instance, in the NER, out of the total area of 2.2 million ha of Jhum lands, about 17.5% is cultivated at any one point of time, involving about 4.5 lakh Jhumia families. Of late, with increasing awareness of disadvantages of shifting cultivation, the farmers in certain areas have started adopting settled cultivation. Some of the pilot projects like (a) Permanent settlement of Jhum cultivation through development of plantation crops in Karbi Anglong and N.C.Hills of Assam, (b) Providing 2.0 ha of terraced land to Jhumia families along with inputs and financial help for settled cultivation in Meghalaya, (c) Land reclamation and provision of production inputs for horticulture and cash crops in Mizoram, and (d)
Encouragement for terrace cultivation in Nagaland and others are already showing some positive impact towards settled cultivation.

4.1.4.7 Also, emergence of a trend of land concentration in the hands of a few and privatisation of land holdings have been reported from some areas. In the name of tribals, some ‘smart’ tribals are cornering community lands in their personal names. Such pitfalls should be warded off. Presently, the valley lands, terrace lands, homestead lands and short-fallows are being recognized as private lands for all practical purposes. In Assam, the State has proper land records, particularly in the plains, while in Manipur the entire valley has been covered under permanent ownership. The Land Reform Act, 1960 of Tripura is perhaps the most comprehensive one, in which (i) land ceiling, (ii) prevention of fragmentation of land, (iii) restrictions of land transfers from tribals to non-tribals, and (iv) non-eviction of share croppers in general have been covered.

4.1.4.8 Crop diversification and commercialization of agriculture are yet to emerge in economy scale, except in certain plantation (tea), spice (ginger, large cardamom) and tuber (potato) crops. As per estimates of the National Horticulture Board (2003), the NER produces 2.6 million tonnes of fruits from 0.287 million ha and 4.00 million tonnes of vegetables from another 0.38 million ha. Three plantation crops viz. tea, coffee and rubber cover 3.33 lakh ha area. Rubber with an area coverage of about 45 thousand ha and coffee with about 10 thousand ha are recent introductions, thanks to the efforts of respective Commodity Boards. Small scale cultivation of tea in Assam spreading over 40 thousand ha is a new innovation integrating small landholders in tea production system. Rubber with an area of over 25 thousand ha is already a source of revenue to the State economy of Tripura. Tea, Coffee and Rubber Boards have planned a number of schemes to promote these crops under small-holder sector.

4.1.4.9 Hills and mountains of varying altitudes and temperature regimes provide excellent niches for production of quality seeds of temperate and sub-tropical vegetables. Women Self Help Groups for vegetable seed production in the hills should be formed, trained and empowered to undertake commercial production and distribution of vegetables seeds. Leading seed companies, which could provide backward linkages
with technologies and inputs and forward linkages with processing, packaging and marketing, should join hands with the producer groups under a transparent contract farming arrangement. NABARD and other financial institutions should particularly be interested in promoting such initiatives.

4.1.4.10 Himalayas are great reservoirs of biodiversity. For instance, the NER is considered as the Centre of Origin of certain species of mango, citrus and banana. Many wild species and primitive land forms of tropical vegetables like cucumber, brinjal, gourds, beans and bhindi are available in the region. Rich genetic diversity has also been reported for crops like yams (Dioscorea spp.), ginger, medicinal and aromatic plants like Aconitum, Penax, Terminalias, Cymbopogon, Cinnamomum etc. A large number of ornamentals and flowers are found to grow in wild and semi-wild conditions and about 600 species of orchids are flourishing in the region. The cold deserts of NW States also possess unique biodiversity of livestock (Yak), cold fishes, temperate fruits, medicinal plants and microbes, which is largely underexploited.

4.1.4.11 Most of the indigenous species of different horticultural crops have not been exploited fully. Certain polyembryonic mango types have been reported from Manipur and Tripura but no serious effort has been made for their use. Seeded banana has been domesticated and consumed locally. Some of them have high baby food value. In citrus, ‘Assam Lemon’, a lemon-citron type, is grown largely but the Satkara (C. macropertera), ginger flavoured ‘Adajamir’. (Cassamsensis- Dutta and Bhatta), ‘Soh-Jew’ (a probable sour mutant of C. limettoiodes) and the acidulously sweet citrus types like Soh – Nairiang and Soh-bitara of Meghalaya and Tasi of Arunachal Pardesh are enjoying only very limited commercial value. They need to be exploited more both for table as well as processing purposes.

4.1.4.12 Several indigenous vegetables, not common in other parts of the country, are consumed locally by the tribals. Tree-bean (Parkia roxburgi), known locally as ‘young chak’ is in good demand in Manipur, while the tribals of Tripura grow a species of Vigna (V.uexilata) for edible pods and tubers. Winged bean (Psophocarpus tetragonolobus) are liked in Mizoram, Nagaland and Manipur, while the roots of a
tropical legume (*Flemingia vestita*) known as ‘Soh-Phlang’ is often consumed by the Khasis in raw forms. Medicinal plants like *Rauvolfia serpentina*, *Solanum rhasianum*, *Dioscorea prazeri*, *Coptis teeta* are widely available in the region but not fully exploited commercially. Orchids as medicinal agents have been used by the tribals of the region and in the Khasi and Jaintia hills of Meghalaya alone about 50 species of orchids are reported to be used for different ailments. The crushed leaves of *Cymbodium giganteum* is used for clotting of blood, while the juice of *Vanda coerulea* flower is used as eyedrop for cure of glaucoma. **The wisdom and long experience of local tribals have hardly been gainfully used and not much has been done to refine the indigenous knowledge through scientific experimentations, let alone the poor documentation of the indigenous and traditional knowledge.**

4.1.4.13 The perennial horticulture and plantation crops are high value crops and help in checking soil degradation in the hill slopes. Soils of hills and mountains being rich in organic matter and certain other plant nutrients, some horticultural and plantation crops can be grown organically with minimal use of chemicals. The programme to produce organic tea in certain areas may help add further value to the produce and prove to be economically more remunerative.

4.1.4.14 The North East Hill region has unique advantage of geographic proximity to South and South – East Asian markets like Bangladesh, Maynmar, Nepal, Bhutan, Singapore, China and Thailand. The proposed “The India – Thailand Highway” through Myanmar will enhance sub-regional co-operation and the large markets of S.E.Asia will be much closer to NER. **Cross-border integration through promotion of conducive market oriented agriculture must be aimed.** This calls for definite plan and strategy for development including programme prioritization, integration and implementation.

4.14.15 The creation of the Ministry of Development in North Eastern Region signifies the commitment of the Government of India to accelerate the pace of socio-economic development of the region. As per the work allocation of the Ministry, the North Eastern Council (NER) and North Eastern Regional Agricultural Marketing Corporation Limited (NERAMC) are directly involved in activities related to agriculture
development in the region. In addition, other nodal Departments of Ministries of Agriculture, Commerce and Food Processing Industries are directly involved in promoting agriculture through developing and funding various projects. The technology mission for integrated development of horticulture in the NER is one such plan programme of DAC of MOA in the recent past. A significant amount is already assured by earmarking 10 percent of the Plan Outlay of the Central Government. Notwithstanding the substantial support of the Central Government to the North East and to Jammu and Kashmir in the North West Himalayas, often for obvious political reasons, **the States have generally failed to plan systematically and allocate necessary financial and other resources to agriculture and rural development from their own exchequer.** The paucity of adequately trained human resources is further aggravated by the prevalent non judicious deployment of the resources. It all boils down to the issues related to transparent governance ensuring rational investment in development and timely flow of adequate funds and other resources to the action site without transmission loss.

4.1.4.16 The NABARD has developed a special package for the North East, both for production credit and investment credit, including concessional rate of interest and higher allowance for refinance (upto 25 % of NPA as against 15 % in the country as a whole and for thrust areas even 100 % refinance allowed). NABARD’s current activities cover many items such as CAT (Capacity building for Adoption of Technology), SHG programmes, Organic farming etc. which are highly relevant for NER. Similar packages are available for the individual NWR States.

4.1.4.17 For Assam, the Regional office, NABARD has formulated model bankable schemes on Patchouli, Safed Musli, vermi compost, Jatropha biodiesel plantation and others. It has also proposed organization of SHGs for hill people. The roles of VDBs in the hill districts in identification of borrowers and recovery of loans have been emphasized by NABARD, since VDBs have considerable influence over the villagers. Earlier NABARD had tried to channelise credit for rehabilitation of Jhum lands in Mizoram through Teak Plantation Forestry but did not succeed due to non-availability of land records. Credit deposit ratio is generally low in the NER and credit outcome need to be measured, for which NABARD should institute studies through its R &D sector.
4.1.4.18 The North Eastern Development Finance Corporation Limited (NEDFi), a premier financial institution of the country, also helps in development of agriculture in NER. It has micro-finance schemes for providing financial assistance to NGOs and SHGs. Similarly, North East Equity Fund (NEEF) has also been created to help first-generation entrepreneurs. NEDFi has taken up initiatives in promoting medicinal and aromatic plants in NER. Due to NEDFi support, Patchouli cultivation has spread over 1800 acres. It has so far financed 222 projects in agriculture and allied sectors with an estimated project cost over Rs. 26 crore. Under micro-finance, it has supported almost 25 NGOs and over 2000 SGHs. NEDFi’s future programmes cover financing contract farming and rural micro-enterprise development.

4.1.4.19 APEDA is providing airfreight subsidy for transportation of horticultural commodities from any State of NER to Kolkata. For floriculture crops, the freight subsidy is even upto 90 % of the fare. All other APEDAs export promotional schemes are equally applicable for the NER. APEDA has already developed ‘Agri-Export Zone for Orchids’ in Sikkim, in which all concessional provisions are available.

4.1.4.20 NEC provides project finances to NGOs and SHGs to promote floriculture sector, while to develop high quality commercial horticultural farms the promoters may avail credit linked back ended subsidy from National Horticulture Board (NHB) @ 20 % of the total project cost with a maximum limit of Rs.30.0 lakh per project. United Bank of India (UBI) is mainly financing tea gardens and has special schemes for transport subsidy upto Kolkata. The State Bank of India (SBI) targets to cover one lakh families in NER and considers SHGs as a preferred way for bank credit flow as the risk is comparatively low. SBI has provided financial support for passion fruit cultivation and for floriculture (Anthurium) projects in Nagaland. Further, it is contemplating to provide support to apple and Kiwi cultivation in Arunachal Pradesh.
4.1.5.0 Pathways for an Agriculture-led Sustained Prosperity, Peace and Happiness of Hill People

4.1.5.1 The Green revolution has failed to climb the Himalayan heights and agriculture in Indian hills has, by and large, remained at subsistence level. Majority of the hill States have relatively high concentration of poor and malnourished people. This is ascribed mainly to wrong policies, scarcity of cultivated land, increasing demographic pressure and poor access to technology, credit, market and infrastructure. Immediate measures are required to address these constraints towards sustainably improving livelihood security of hill people and for arresting and bridging the widening socio-economic gaps between the “lowlands” and the “uplands.”

Call for a Major Paradigm Shift towards Knowledge-based Development of Hill Agriculture and Hill People

4.1.5.2 Much of the development efforts made in the hills in the past were based on poor understanding of the hill/mountain conditions, resources, environment and the socio-cultural settings of the people. The mainstream thinking was dominated by the degraded marginal sloping lands, biases against hill farming, marginal land based limitations, forest conservation as priority and the like. The hillside development policies focusing on forest cover through regulation had excluded local users across a wide range of ecological and socio-economic regimes. Many of these perceptions were perhaps unfounded. To put the things in right perspective, our overriding recommendation is to undertake fresh interdisciplinary studies on the Himalayas to generate new data and information about the state of the development process to guide the new efforts on improving livelihoods of hill farmers.

4.1.5.3 The sustainability prospects for mountain agriculture remain bleak unless the mainstream perceptions about the problems are changed. While the development thinking in the hills views marginal mountain lands as a constraint, for the hill farmers marginal lands are a given condition and diversified livelihood options have been evolved to capture the niches and comparative advantages of available natural resources, namely, mixed farming, nomadism, swidden farming, ecotourism, etc.
4.1.5.4 Farming alone is unable to meet the food and livelihood needs of the families inhabiting hills; therefore they employ multiple livelihood strategies through diversification of household activities. However, these options are also giving diminishing returns and hill farmers are looking for new alternatives. **Unemployment is widespread particularly across the Himalayan States—large force of educated unemployed rural youth from farming families is waiting for opportunities.** On the one hand, demographic pressure on cultivated land is increasing, rendering the already small holdings still more fragmented, uneconomical and unsustainable. Through educating and sensitizing people, **while population growth rate must be reduced, off-farm and non-farm employment opportunities must be created to reduce the pressure.** Off-farm employment should be a major policy element, especially for retaining the young educated masses in rural areas.

4.1.5.5 The development of sustainable hill agriculture systems requires that development planning processes follow certain guiding principles. **The best model of hill area development is to have its sustainability embedded in ecological protection, cultural heritage and human development,** encompassing the following guidelines:

- **Recognize diversity of land, water and bioresource use opportunities**
- Identify and harness location-specific niches
- Hills are less suited for uni-dimensional land use, but more suited to multiple strategies that consider unique characters of smaller sites within the whole landscape; ensuring a balanced relationship between people and land resources
- Productivity is not only based in the biophysical characteristics of hill lands, but also depends on the socio-economic parameters and cultural milieu of a hill environment
- Marginality of mountain and hilly areas is not a static concept, it is a dynamic process; technologies may be known but the other necessary incentives, institutions, or inputs may be missing and need to be dynamically adjusted.

4.1.5.6 It must be stated that much of the woes of hill farmers, apart from poor access to resources, are due to inappropriate technological research and extension interventions.
Only if we take bold steps to restructure and reform agricultural research and technology efforts to bring them in line with the needs of hill farmers—most of the woes of hill farmers would have been solved. **No amount of policy reforms and enhanced plan allocations and investment will make much difference unless right technological pool of options is offered to farmers.** Let it be said that hill farming has added to degradation of water and land only in areas where new technologies were introduced and adopted in a straight-jacketed fashion. Indian agricultural institutions fall much behind in perceptions of hill farming — the integrated approach, planning technological research that is need-based and in providing technological options which are both ecologically and economically desirable. There is in fact little ecology in agricultural science of India today and this gap has shown adverse effect in more marginal areas. **Ecotechnologies for alleviation of ecological poverty and hunger should particularly be emphasized for agriculture-led development of hill people and agro-ecology should be emphasized particularly in the hill agricultural universities’ curricula.**

**New Policy on Hill Agriculture**

4.1.5.7 At the national level there is need to adopt a differentiated approach to hill area development. Hill areas agricultural development objectives in particular and overall hill area development in general are definitely different from plains area goals. The strategic national needs from hills are both products and services. Services are largely relating to conservation of physical resources in the national interest and there is little appreciation of the humanware. The present policy and planning perspective has a major drawback in the sense that there is no recognition of the fact that hill people play important role in providing ecological services to the nation – conserving land, water and most important biodiversity. **There has to be a national policy on compensating citizens for their ecological services they provide to the civic society.** Tools are now available to calculate the economics of ecological services offered by a community, a regional government and state government or even by a farmer. WTO also supports this strategy of compensation and that is what Switzerland and European Union is doing under its new agricultural policy. The new EU policy frame supports compensation for farmers who
contribute to maintain ecological balance through good agricultural practices, keeping land water and air clean.

4.1.5.8 Keeping in view the unique and special agro-ecological and socio-economic settings and recognizing that hill agriculture has not benefited to the desired extent from the various technological and developmental efforts, the National Policy on Agriculture should have a special parallel, yet integrated, window on hill agriculture so that commensurate strategies, programmes and activities for hill agriculture production, research, technology development, extension, human resources and product development and marketing geared towards socio-economic and agro ecological synergy leading to well being and happiness of hill farmers could be established. Mountain-specific agriculture-led developmental approach should be the main point of hill States’ relationship with the Government of India.

4.1.5.9 The Consultations held in the NER (Shillong) and NWR (Shimla), as also in New Delhi, emphasizing the various issues and opportunities discussed above, strongly recommended formulation of a sustainable hill agriculture and mountain development policy at the national level in which central role of agriculture is duly elaborated and harmonized with environmental and livelihood security. While efficiencies of the various programmes such as the Western Ghats Development, Eastern Ghats Development, Deccan Plateau Development as well as the Ministry of DONER, etc. should be enhanced, their outcome could be synergised by creating a National Programme on Hill and Mountain Agro-Ecosystem to coordinate all the concerned programmes of the Government of India. The Coordination Mechanism should preferably be housed in the office of the Prime Minister, with close linkages and interactions with the Ministry of Agriculture, Ministry of Development of the North East Region, Ministry of Environment and Forests, Ministry of Rural Development as well as with the National Development Council. The various existing funding and financing mechanisms such as NABARD, NEDFi, NERC, etc. should be coordinated and synergized and their scope expanded under this umbrella as a National Hill and Mountain Agro-Ecosystem and Livelihood Development Fund.
4.1.5.10 The interdependency and synergy between all sectors of agriculture *viz.* crops, horticulture, livestock, fisheries, forestry and the associated natural resources should be strengthened. One cannot be excluded by the other. Explicit policies on rights of tribal people on forests and forest lands should be formulated. In doing so, the positive role of the forest dwellers in forest and ecosystem conservation, such as the Chipko Movement, should not be ignored.

4.1.5.11 Given the poor accessibility, necessary structural and management changes should be effected towards sustained self-reliance of hill villages to attain true Gram Swaraj of Mahatma Gandhi. Policy changes are equally needed in the management of wild life and tree harvesting, agro-forestry and utilization of non-timber forest produce. The policy statement should explicitly mention that socio economic and cultural milieu and indigenous knowledge of hill people should constitute the basic fabric of the efforts towards sustainable livelihood security of hill people.

4.1.5.12 More secure land rights may be one of the necessary preconditions to stimulate investments among farmers. The rights must equally be granted also to women farmers who often shoulder the bulk of the agricultural work. An enabling policy environment is essential in order to recognize and to strengthen potential developed at the grassroots’ level and to encourage people-based initiatives in different areas. Changes are needed in law where it denies access to and use of sloping land resources that are basic to the livelihoods of local people. Shifting cultivators and agro-pastoral communities need that attention more than any one else.

4.1.5.13 Investments and capital formation in agriculture are at an all-time low, adversely affecting agricultural growth and development. The situation is particularly unsatisfactory in most hill States, especially in view of high costs of provisions of infrastructure and services inherently associated with hill regions. Policy to ensure additional investments in research for creating necessary infrastructure and also technology development is required to create a basket of choices of suitable production systems capturing every niche and for strengthening livelihood security. The concerned
State Governments must enhance their investments in improving and sustaining the agro-ecosystems.

4.1.5.14 Explicit policies are called for utilization of fallow, degraded wastelands and deforested areas and for promotion of PPP in judicious equitable and sustained use of these resources. Policy guidance on Jhuming will need to be made much more farmer friendly. Land tenureship and right issues should be sorted out as soon as possible.

4.1.5.15 The New Policy on Hill Agro-Ecosystem and Mountain Development should capture commonalities and comparative advantages, synergy and scale of economy options and geo-political consideration. In this context, we may look east and learn from Japanese and South Korean experiences on strengthening hill agriculture. Japan’s new policy on agriculture “considers declining hill agriculture as a national loss”. The thrust of the new policy and the newly enacted Mountain Village Development Act is on reversing the trend of declining mountain farming communities and conserving hill agriculture, rather than forests (Box 4). Likewise, the South Korean Marginal Land Improvement Programme (MALIP) for hilly and mountain areas under its Farmland Law emphasizes the necessity of both ecological and economic considerations (Box 5).

Food, Nutrition and Income Security

4.1.5.16 The hill regions are characterized by small and marginal holdings and resource-poor farm families. Employment security is also poor. The smaller the farm, the greater is the need for marketable surplus, so that the farm family will have some cash income. Therefore, accelerated progress in enhancing the productivity, profitability and sustainability of the major farming systems is the best safetynet against hunger and poverty. The major objectives of the agricultural strategies in the hills should be nutrition security of every child, woman and man, income security of farm families and enhancement of ecological foundations.
Box 4

The mountain people and policies in Japan

Japan has over 68% of its total area as hilly area, which 30 per cent contained of the cropland of the nation. After decades of neglect and biased against hills, agriculture and people inhabiting the hills faced uncertain future. Hill agriculture in Japan faced difficulties of social nature. Alarming rate of households were abandoning hill farmland and over 3.8 per cent of the nation’s farming area was abandoned by 1998. As a result, hill-farming communities of Japan faced problem of extinction due to decrease in agriculture and increase in forest area, depopulation and aging of residents. As industrial growth offered ample job opportunities for younger generation of hill farmers, they seemed no longer interested to continue farming their family land.

The factors responsible for declining hill farming in Japan included: decline in the number of farmers and their advanced age; concerns over future prospects of liberalized agriculture trade; decline in job opportunities; delay in social capital infrastructure development; small land parcels making mechanization difficult; intricate topography and small size of land holdings; lack of adequate access roads limiting use of farm machines; higher costs of land grading, irrigation etc. The implications of the rising rate of abandoned farming included increasing national food insecurity; loss of crop resources; and loss of indigenous knowledge of hill farming, threatening Japan’s long term national food security interests and posing the question as to, who will know how to farm the hill lands tomorrow?

Having realized the gravity of the situation, Japan made a turn around. Today, “as a matter of new policy, Japan considers declining hill agriculture scenario as a national loss.” It is making serious efforts to reverse this trend. The Depopulated Areas Emergency Act and the Mountain Villages Development Act have been put into effect for conserving hill agriculture, rather than forests. The policy aims to realize balanced development of industry through improving the environment, social welfare and traditional agriculture. To support niches based high value farming and income generating options for the hill farming communities R&D support is focusing on: vegetable farming and floriculture with special highland products; animal husbandry on grasslands; labour intensive organic farming; developing forestry; micro enterprises development – food processing etc adding value to the local farm produce; changing tourism development approach to build stronger tourism-farming linkages “farming for tourism”. The Shikoku National Agricultural Research Station has been mandated to focus its research on “slope land agriculture”. The thrust has been on reversing the trend of declining mountain farming communities and conserving hill agriculture.
Korea has 66 per cent of its total area as hill areas which contain 33 per cent of the farmland of the nation. Korea has been promoting the policy of “Agricultural Promotion Area (APA)”, which favoured only plain areas for agricultural investment priority. Hill agriculture falling under “Less Favoured Areas (LFA)” was thus neglected for investment. As a result, Korean farmers living in the hills found it harder to survive under poor production conditions. The quality of life in the hills was certainly lower than that in cities, encouraging younger generation of farming families to leave farming and farmland for jobs and better livelihoods in the cities. The hardship of upland farmers was further compounded by the shortage of farm labour because of job-induced migration of young upland folks to urban areas. It was a key factor that contributed to accelerated abandonment of agriculture and farmland in the Korean uplands. As an example, in 1993 alone over 66,500 hectares of cropland was abandoned, which was 3.2% of the country’s total cropland. By this rate nearly half a million hectares of cropland in the hills would have become abandoned by the year 2000.

Korea made a shift in its policies, considering that even if hills are less productive, continuing farming on these lands may yield higher positive externality to society than favourable production condition areas. Higher the positive externality of these marginal areas, higher will be the price and percentage of tax payers “Willingness To Pay (WTP)”, so as to maintain farming in the marginal upland areas. The trend has encouraged the government to consider reshaping of the policy of agricultural promotion zone for investment and now it has included hill areas also in it. Thus, Korea has adopted a unique tax policy for city dwellers, called “Willingness to Pay” and uses the revenue generated for improving farming and livelihoods in the hills.

Farmland Law of 1994 and Rural Improvement Law of 1994 were other steps taken by the government. One of the more relevant programmes was – “the Marginal Land Improvement Programme (MALIP)” for hilly and mountain areas. It was two-dimensional. One, it was to improve the use of marginal upland as productive land; two, it was to promote use of marginal upland for other farm and non-farm purposes; such as, rural resorts, livestock farming, fruit farming, and industrial development. Further, a scheme for compensating mountain farmers through direct cash payment to continue farming their farmlands was also introduced. It had two key objectives, increase food supply and preserve traditional farming areas on hill landscapes.

The lessons of the Korean experience may be summed up by as when the agricultural policies and measures consider only economic values, they are not sustainable and future generations may suffer access to resource base. Therefore, the policies favouring direct and indirect support to maintain hill farming are necessitated by both ecological and economic considerations.”

4.1.5.17 A whole life cycle approach to the implementation of all nutrition support programmes should be introduced, and horizontal linkages should be established among numerous vertically structured programmes which are currently being
implemented. SHGs can be enabled to establish at least 500 Community Food Banks using locally grown grains as well as grains of under-utilized crops such as millets. Such SHGs should establish forward linkages with markets and backward linkages with Agricultural Universities and Research Institutions, so that they can become technically competitive and economically sustainable.

4.1.5.18 The Hill States should take full advantage of the National Employment Guarantee Scheme (NEGS) along with the Food for Work Programme (FWP) to achieve comprehensive food and nutrition security under the proposed National Food Guarantee Act. The NEGS must be used for creating productive assets and encourage capital formation. In order to achieve greater employment security, both skilled and unskilled employment should be promoted. Tourism, especially health, spiritual and adventure tourism, holds great promise in the hills and mountains and should be actively promoted. For ensuring convergence and synergy among various ongoing programmes, it will be useful to set up a Hill Farmers’ Council for Sustainable Food and Livelihood Security as a consultative and monitoring body on food and livelihood security which could be a part of the national alliance for elimination of hunger and poverty.

**Bridging Information Gaps on Key Indicators and Establishing Village Knowledge Centres**

4.1.5.19 Deploying latest GIS techniques, areas of hills/mountains, the existing land use patterns, including those of different gradients of slopes, under various categories of forests and degraded lands, and the like, should be measured and delineated as the highest priority. In the absence of up-to-date and accurate information on such vital aspects, policies, strategies, plans and programmes on hill development and on hill agriculture will be elusive and misleading. With the increasing population pressure on hill lands and hopefully with the prospects of rights of tribals to own at least the degraded forest lands (which may be helpful in checking further degradation), the stipulated information is a prerequisite for undertaking knowledge-based allocation and deployment of natural resources to the needy people. Public action is urgently needed to create task forces and research groups, involving major stakeholders, and to provide
necessary facilities to such groups to undertake participatory research to analyze the cause-effect relationships among the various agro-ecological factors and status of soil and water loss/erosion, overall environmental and ecological degradation and deforestation, etc. This work is urgently required to enable the country to correct and avoid the past “mistakes” and to formulate and implement **people-centric** policies and programmes. This will also help promote synergy and convergence among agriculture, forestry, ecology and economy.

4.1.5.20 Under the national movement for creating each village as a knowledge centre, and with the passage of the Bill on Right to Information, especially realizing the geographic isolation, inaccessibility, remoteness and poor connectivity in the hills and mountains, high priority should be given to the creation of Village Knowledge Centres (Chapter VIII in the First Report of the NCF). Contents of the information package, besides being dynamic, relevant and user-friendly, should have up-to-date information on markets, trade, prices, new technologies especially on organic agriculture, biodiversity management, traditional knowledge, medicinal and aromatic plants, and weather outlook and risk management. SHGs, especially WSHGs, and the rural youth should particularly be associated with this movement. The public sector and financial institutions should supplement necessary funding requirements, at least in early stages, and help develop human resources. The National Alliance for Rural Knowledge Centres, NABARD, the North Eastern Space Applications Centre and similar establishments in the North West Himalayas, such as the DRDO Centre in the Cold Arid Zone of Ladakh should work together for establishing Rural Knowledge Centres in the hills.

**Location-specific Planning and Monitoring**

4.1.5.21 Action plan to suit different physiographic and agro climatic zones should be drawn up. In the different regions, action plans should be based on the following five major agro climatic zones – Tropical, Sub-tropical, Temperate, Intermediate and Cold Arid. The objective of the Action Plan should be to maximize the benefits from the different agro-climatic endowments of the States and minimize hazards and risks. Also, a strategy should be designed to promote job-led economic growth through greater
attention to agro-processing and agribusiness. The Hill State’s comparative advantage lies in their ability to grow a wide range of fruits, nuts, ornamentals and specialty crops including olive, apricot, apple, walnut, kiwi fruit, avocado and medicinal plants. This advantage must be capitalized through creating specialized groups and adopting an end-to-end approach, linking production with marketing. Restructured Land Use Boards, matching agro-ecological, socio-economic and marketing capabilities and opportunities, should play an important role in advising the farmers about the prospects of different crops/varieties, livestock/breeds, etc.

4.1.5.22 **The State Governments should revitalize their Land Use Boards to play the much needed proactive advisory role.** It must be emphasised that land use decisions are also water use decisions. Therefore, in order to be able to provide an integrated advice, meteorological, ecological and marketing (domestic and export) factors would have to be considered simultaneously and interactively. Such a Board could be located in an Agricultural University and through a virtual college should give proactive advice on the choice of crops and farming systems, so as to achieve a match between demand and supply in farm commodities and to ensure that the most efficient crops are grown in different agro-climatic and agro-ecological regions.

4.1.5.23 The various Hill Area Development Programmes (HADP), including EGDP, WGDP and DPD, have met with varying successes in the different States. Lack of proper planning and judicious use of local resources have resulted in poor outcomes. The impact of the Programmes should be critically evaluated and reviewed to: (i) identify achievements and failures, clearly identifying the elements of successes and failures, (ii) suggest strategies and measures for wide adoption of the successful experiences and propose effective and easy-to-adopt evaluation and monitoring mechanisms and necessary remedial measures for avoiding the failures, (iii) undertake detailed agro-ecological and socio-economic studies in different agro-ecosystems and (iv) recommend policy framework and governance mechanism, including State-Centre coordination, flow of funds to the action site and accountability and increased commitment of the States for meeting the aspirations of the people of such disadvantaged areas. Since a large number
of schemes sponsored by Government of India are operational and funds from various sources are supposed to converge at the same action site, an institutional mechanism should be established or empowered, if not already existing, such as PRIs, to ensure synergy.

4.1.5.24 **Under the HADP, the level of satisfaction among the population with the pace of development is rather poor.** In view of the poor allocation of funds to these areas, the expenditure tends to be thinly spread without creating any serious impact in the ecology and environment of the area. **While the States must have the necessary flexibility to design programmes under the various special area development programmes, there is a need to prepare a perspective plan for these areas over a ten-year programme so that at least at the end of that period, these areas can be brought on par with the rest of the State.** On the implementation side, it is absolutely necessary to ensure people’s participation primarily through the Panchayati Raj institutions at the local level. The assistance of credible NGOs wherever available could be tapped. In the Western Ghat region, there is a need to plan and implement a comprehensive integrated watershed development programme in a time-bound fashion rather than continuing with the present practice of thinly allocating the available resources by taking up so many sporadic programmes in different sectors and areas of the region, as mentioned earlier.

4.1.5.25 Hill farmers in border areas are subjected to additional vagaries of war and tension. Under the Border Area Development Programme (BADP), Special Central Assistance is provided as 100% grant for execution of approved schemes in border blocks. Often, the works are implemented largely in the block headquarters. In order to ensure that the villages which are actually on the border benefit from this programme, a change in the spatial unit of the programme to border village Panchayats instead of the border blocks may have to be considered. To ensure that the schemes are not taken up every year on an *ad hoc* basis, there is a need to draw up a perspective plan for implementation under BADP, keeping in view the flow of funds under both the normal
State Plans and the BADP. The decision-making process also has to be decentralized by involving the representatives of the Panchayati Raj institutions at the appropriate level.

Jal Swaraj: Hydrological Balance and Water Security

4.1.5.26 The Himalayas, with snow cover varying from about 1 to 3 million km$^2$ and around 100,000 km$^2$ glacier cover, constitute the water towers of India. Recent model studies show that, without the present Himalayas, the temperature over Southern Asia would have been 12$^0$C higher and there would have been no Indian monsoon. Moreover, the glaciers melt water contributes 400 to 800 km$^3$/year water to Indus-Ganga-Brahmaputra river system - the life line of agricultural security of the country. With such a favourable hydrological regime, one would expect Himalayas and water basins of its rivers to be fully water-secure. But unfortunately, this is not the case; per capita water availability in the country is likely to go below the scarcity level by 2025.

4.1.5.27 The normal rainfall in the Himalayas varies from 900 mm in J&K to more than 3000 mm in Assam and Meghalaya. Although abundant, the rainfall is highly erratic both in time and space, and most of it falls in less than 100 hrs as a result of which less than 30 per cent is retained and the rest is lost as run off etc. Cherrapunjee, located in the State of Meghalaya, has the world’s highest average annual rainfall of over 11,000 mm. Paradoxically, this wettest place in the world experiences scarcity of drinking water in the summer months. This harsh reality highlights the most obvious need to conserve and harvest the rainwater.

4.1.5.28 Another limitation of the hill region is that the hill soils are shallow, thus prone to erosion. This does not permit higher retention of water by soil, leading to run off, siltation of dams and floods. Harvesting of rainfall becomes essential also for reducing the run off which also removes the nutrient enriched topsoil.

4.1.5.29 Against the backdrop of the huge water resources, less than 20 per cent of the cultivated area in the hills is irrigated, as compared to the national average of about 40 per cent. Hence, there is need and scope for increasing irrigated area in the hills for
enhancing productivity and income. **Hill water policy thus must emphasise the integration of farm level, watershed level, agro-ecological zone level and the national level water security.** In this context, we have to address two major interdependent issues towards achieving our jal swaraj (water self-reliance). The first one relates to the harvesting of rainwater, groundwater recharge and judicious and sustainable use of the water. The second one (of long-term consequences and implications) relates to the hydrological balance in the Himalayas as dictated by the snow and glacier regimes and the climate change.

4.1.5.30 As regards the first issue, there are several mutually reiterative approaches to address it. **One of the options is to create water harvesting structures.** It is proposed that water storage tanks of 15 cu m capacity with or without water delivery systems can easily bring one ha under irrigation. Perennial streams which are a major feature in these regions can be tapped to feed the tanks. The approximate cost of these structures are given in (Table 8). These tanks can best be used for gravity based pressurized drip/micro sprinkler systems.

**Table 8. Cost estimates of providing water using 15 cubic meter water harvesting structures with drip irrigation system**

4.1.5.31 Rain water harvesting in small lined farm ponds and the storage tanks need to be taken up more vigorously. The farmers must be educated and trained accordingly and should be provided with adequate need-based subsidy for the construction and maintenance of lined farm ponds and tanks. Another simple method of harvesting and utilizing rain water for domestic and agricultural purposes is the roof-top water harvesting, which should be made mandatory in already constructed as well as in the buildings to be constructed in future. Further, the State Governments must take necessary steps to improve the efficiency of the existing Lift Irrigation Schemes (LIS) and to extend it to new potential areas.

4.1.5.32 *Kuhl* (small gravity streams) irrigation is the age-old practice and the major irrigation system in hill states. For instance, it covers about 92% of the irrigated area in Himachal Pradesh. Specific measures to enhance the potential of the existing *kuhl* irrigation system need to be implemented. At site specific locations new *kuhl* structures are required to be laid to increase the area under irrigation. Varabandi (fixation of time) system of water distribution needs to be strictly taken up in the *kuhl* irrigation system, as the farmers at the tail end do not get their share of water while the farmers located at the head reach generally over-irrigate their fields. *Water User Associations*, with active involvement of PRIs, should be established to ensure equitable distribution and effective maintenance of the water system.

4.1.5.33 For the most judicious use of irrigation water, thrust has to be laid on pressurized irrigation systems, which would help not only in covering wider areas in the characteristic undulating farm lands, but will also increase the water use efficiency in crop production. It is proposed to cover 200,000 ha under micro-irrigation in the Himalayas during the next 7 years. Hilly regions are tailor-made for promotion of high value horticultural and plantation crops, and, as these crops are ideally suited for drip/micro- sprinkler systems, there is high complementarily between the hill cropping system and the micro-irrigation/ fertigation system. The hill States have generally failed to benefit from the GOIs programmes and financial supports to micro-irrigation.
Wherever adopted, the systems have not performed well due to faulty hardwares supplied under subsidy-supported programmes. This sluggishness and opaqueness should be remedied urgently. Strict quality control measures should be adhered to maintain the efficiency and credibility of the system.

4.1.5.34 Activities such as road construction, mining, tunnelling, building construction, deposition of spoil/debris, blasting etc., if taken up non-scientifically, change the hydrology of the region and generally disrupt the availability of natural water resources, such as springs, wells, nullahs, kuhls etc., besides damaging the environment. While taking up such activities the concerned Government agencies must interact and intervene (if required) considering the hydrological repercussions.

4.1.5.35 Special steps will have to be taken to rehabilitate hydrologic “hot spots” and water bodies like Dal and Wular lakes and in J&K. Low Water Parks should be established to demonstrate as to how to increase income per litre of water. There is scope for groundwater exploitation in the hill, but this is expensive. Low Water Parks involving both the cultivation of high value but low volume and low water requiring crops and the use of fertigation and micro-irrigation techniques will help foster water literacy, increase water use efficiency and save the precious water. The approach has to be a watershed plus system. Low cost greenhouses using fertigation techniques should be popularized. The National and State level bodies, especially the Land Use Boards, should render proactive advice to stakeholders on crop planning in accordance with meteorological and marketing factors.

4.1.5.36 The role of agricultural implements and machines in enhancing water and labour use efficiency has remained negligible, and this drawback needs to be urgently corrected. Fortunately, precipitation harvesting technologies have already been developed but need to be promoted with due consideration to the stability of slopes and erosion problems. Water harvesting and storage involving use of pond lining materials will also promote fisheries in the hills to further augment food, nutritional and employment security.
4.1.5.37 The declining ground water table is likely to become a serious issue in hills as well. To check the problem, appropriate groundwater recharge measures must be enforced by all stakeholders. The traditional systems of rain water harvesting, groundwater recharging and water use, such as the system of the Kohlis and the Phad irrigation systems of Maharashtra and the Korambu system of the Eastern Ghats, should be protected, popularized and further improved.

4.1.5.38 There must be nodal agencies at State and National levels to develop databases on water resource availability and utilization. **Water banks** should be established and operated in areas which are highly vulnerable to water shortages and stresses. Panchayats, SHGs, Water Associations should play the leading role in implementing this programme. The Village Knowledge Centres should be actively associated with increasing water literacy and in promotion of judicious conservation and utilization of the resource.

4.1.5.39 Human resource development will play a key role in implementation of the suggested measures and spreading the message of the importance and awareness of water conservation. Training courses for farmers as well as for personnel of various levels in the water management systems should be an important component of all water development programmes, including micro-irrigation. Interactions with the field workers can also help in identification of low-cost indigenous technologies already prevalent in the hills. Water harvesting is not only essential for agricultural usage alone, it is equally vital for meeting the domestic and industrial water requirement. These demands increase in greater proportions compared to agricultural requirements with increase in the pace of development of a region. Therefore, the water associations and bodies should have representation and active participation of wide range of CSOs, NGOs and other peoples’ organizations towards our goal to achieve and sustain full *jal swaraj*.

4.1.5.40 Turning to the big picture, it has now been conclusively established both through remote sensing and ground truth based investigations that **the glaciers and the snowfields in the Himalayas are on the decline**. The rate of retreat of the snout of
Gangotri glacier demonstrated a sharp rise in the 20th Century. Recently, it has been reported that the Parbati glacier has retreated by 578 metres between 1990 and 2001 (a retreat of 52 metres per year). Excessive melting of the glacier may have a short term impact of making more water available but it will reduce the river flow in the future thus adversely affecting the hydropower projects on the rivers fed by these glaciers. The sudden melting of glaciers can also lead to glacial lake outburst floods and flash flood tragedies as happened in the recent past. The hydrological balance in the hilly regions has a direct bearing on the water resources of the adjoining regions particularly the Indo-Gangetic Basin, having very far-reaching consequences on the nation’s food, economic and ecological security.

4.1.5.41 Global scientific interest in the study of Himalayan snow has been in progress for several years. Expedition mode researches are reported by several investigators, but a systematic scientific exploration of these vast snow and ice fields needs a committed approach. A National Centre on Glaciology should be established following ICU/UNESCO/WMO supported centres on glaciology at Colorado (USA), Moscow (Russia), Cambridge (UK), Zurich (Switzerland) for collection, storage and dissemination of information on status of seasonal/perennial snow and ice. The centre should undertake research on understanding the interaction amongst biological processes, physical environment and the climatic change and develop early, medium and long term warning systems to enable appropriate and timely responses at various levels. The centre, in collaboration with other similar centres, including those on climatology and climate change in the world, should in particular play a proactive role in advising trends of water availability and overall hydrological situation in the medium and long term to enable necessary adjustments in farming system and germplasm utilization.

4.1.5.42 Notwithstanding the centrality of the adoption of integrated water, watershed and farming development systems, the need for integrating uplands with lowlands and pursuing an integrated approach to river basin management can hardly be overemphasized. Such an integrated management system is the result of an iterative process (Figure 1). Under the integrated approach, the objective for the
management of the basin are initially formulated for both the lower and upper basin areas. These objectives should be based on local and national priorities, prevailing land uses and unique characteristic of each basin’s natural resources, thus linking the watershed and flood plain. Such an integrated approach will help not only enriching the natural watersheds and local hydrological endowments, but would also seek a rethinking on the proposed national plan of physically linking all the major rivers of the country.

Objectives are formulated for the management of the entire basin (watershed and floodplain) on the basis of local and national needs by means of intensive stakeholder consultation.

A plan for management of the basin is formulated on the basis of the objectives, the land-use and resource management needs of the area. This is done through intensive stakeholders participation.

The plan is implemented by all landowners and concerned stakeholders under the guidance of a management board supported by appropriate policy instruments and innovative financing.

Implementation of the plan is closely monitored to assess the impact of interventions and policies, if necessary, interventions can be adapted on the basis of the monitoring results.

The implementation of the plan is evaluated on a regular basis to ensure that the objectives are being achieved. If necessary, the objectives can be adjusted in light of new knowledge or a change in user needs.

**Figure 1: The Iterative Process of Integrated Basin Management**

4.1.5.43 Since 1970, several legal systems related to water in India were formulated, such as the Model Groundwater Bill, the Model (Water) Bill, Central Groundwater Authority, Central Groundwater Board and National Water Resource
Council. But, none of these have been effective. A recent study of the Indian Academy of Agricultural Sciences (NAAS) has highlighted the serious gaps in implementation of the various legal provisions and in creating necessary institutions for equitable and sustainable management of water. The Academy has made a set of recommendations to overcome the problems, which along with the recommendations in the above paragraphs 5.29 to 5.41 should be implemented by concerned quarters (Policy Paper 32: Emerging Issues in Water Management – the Question of Ownership, NAAS, June, 2005).

Strengthen the Role of Agricultural Machines and Implements

4.1.5.44 Drudgery in agricultural operations and transport (carrying head load and backload strapped to forehead) should not be acceptable in the modern society. Prevalence of under-nutrition and lung diseases in the hills further aggravates the situation. Hill agriculture is further handicapped due to the lack of adequate engineering and technological inputs. The difficult terrain and climatic conditions do not permit direct transplantation of technologies from the plains. Moreover, women are predominant labour force in hill agriculture. And as we know, ergonomically female workers are not the same as male workers. But, this is seldom considered while designing agricultural machines and implements, causing greater drudgery to women workers.

4.1.5.45 The mechanical power requirements for the hills cannot be met with the existing tractors and power tillers because of difficulties in negotiating the hilly terrains. Light weight power tillers have been envisaged to fulfill the needs. Central Institute of Agricultural Engineering, Bhopal has made an effort to develop a light weight power tiller indigenously and it is being tested. Industrial support to manufacture these light weight prime movers is required along with financial incentives to promote this and other similar power sources. These light weight prime movers could also facilitate the transport of agricultural inputs and produce, as well as for transporting other materials, which are presently being done manually as head loads, with serious health consequences.
There is a need to understand and characterize the hill anthropometrics and accordingly design suitable devices, tools and machines to reduce human drudgery. Ergonomic interventions are essential in hill ecosystems to facilitate faster absorption of engineering inputs in agricultural operations. This will permit not only better work efficiency but also improve human health as the occupational health hazards would have been considerably reduced. The youth in hill ecosystems needs to be sensitized and encouraged to acquire relevant skills to pursue the above-mentioned activities. The SAUs in the region need to orient their curricula to include the appropriate courses on engineering skills required for the hill region.

The land holdings in hill ecosystems are not only small, they are ecologically fragile. Soil and water erosion problems are widespread. To obviate these difficulties, Protective Cultivation Technologies in the form of green houses, low tunnels, mulches and geo-textiles have proved to be effective and even extend the growing seasons in the hills with significantly higher productivities. Greater emphasis needs to be placed to develop regionally differentiated protected cultivation technologies and then promote them on mass scale to create a long lasting impact on agriculture and society.

Post harvest loss reduction and value addition activities are more relevant in hill ecosystems than anywhere else. The difficult terrain and consequent lack of transport infrastructure demands that the agricultural produce is managed well and value addition activities are undertaken in the production catchments so that the transport related problems are minimized. At the same time, the farm incomes and rural employment are enhanced significantly. The development of appropriate post harvest technologies and promotion of agro processing activities are needed to be carried out. For this necessary machines could be imported and/or locally produced and widely popularized. Unit operations that are endemic to hill agriculture and agro-processing should be identified and internalized in research and development activities in the hills, including adaptive alterations in the available machines, tools and implements.
With the above backdrop, R & D institutional support for hill ecosystems should be considered critical. The early establishment of the College of Post Harvest Engineering in Sikkim under Central Agricultural University will go a long way in addressing the issues. This institution along with the Central Institute of Agricultural Engineering, Bhopal; Central Institute for Post Harvest Engineering and Technology, Ludhiana; ICAR Research Complex, Barapani and other existing ICAR units located in the hill ecosystems could be expected to provide the necessary R & D support. Besides, State Agricultural Universities located in hill ecosystems need to be strengthened in terms of appropriate human resource and infrastructure to undertake Agricultural Engineering related activities for the local conditions.

The state Governments need to have effective delivery mechanisms to translate the R&D outputs into outcomes. Specifically, it involves creating agricultural Engineering Directorates in the hill states to assimilate the technological developments and effectively translating them into action. Bases for manufacture, maintenance and supply of farm and agroprocessing equipment should be created in the hills. Networks of custom servicing and agro-service centres run by rural entrepreneurs and SHGs and duly supported by NABARD and other financial institutions should be established. An All India Coordinated ICAR Project on Mechanisation of Hill Agriculture should be launched. The agro processing activities undertaken by farmer and their dependents in the production catchments should be considered as part of agricultural activities, thereby, not inviting taxation.

**Correcting Soil Fertility Imbalances**

Upto 80 percent of soils sampled in the hills show medium to severe micronutrient deficiencies resulting in decline in the growth rate of total factor productivity and in increase of environmental pollution. This hidden soil hunger must be corrected through large-scale adoption of micronutrient supplementation of integrated plant nutrient management system based on soil test. Soil testing facilities should be established at strategic locations, including at KVKs, ATMAs and agriclinics.
and should be duly staffed and equipped to undertake timely and accurate soil testing (see First Report of the NCF). Soil health cards should be issued to the farmers to facilitate judicious adoption of recommended technologies and to monitor soil health. Communities’ Land Care Movement involving local people should be promoted by all stakeholders. The extension agents and farmers should be trained in IPNS and necessary life-saving-support should be provided to the farmers, the SHGs and local communities involved in conserving and judiciously utilizing the natural resources.

**Conservation and Enhancement of Biodiversity**

4.1.5.52 The National Bioresources Development Board, NBPRGR and other concerned organisations should help chronicle and prepare digital inventories of the bioresources of Hill States, covering plants, animals, fish and microorganisms. In addition, these should assist in the sustainable use of the germplasm of medicinal plants, ornamentals and olives, apricots, seabuckthorn, saffron, *kala jeera*, Pashmina goats and yak. Genome clubs should be organised in schools to promote genetic literacy among students. Hill’s unique biological wealth will have to be converted into economic wealth on a sustainable basis.

4.1.5.53 In several hilly areas commercialization of resources is confronting conservation plans. For these farming communities there is need to work out a package of compensation for rendering conservation services. As yet there has been no practice of compensating custodian hill farmers for maintaining the great hill agrobiodiversity. The PVPFR Bill, passed in 2001, should be implemented and hill communities should be empowered to realize the Farmers’ Rights.

4.1.5.54 Although commercialization of forest products can help mountain communities achieve sustainable livelihoods, sustainable use of these bio resources, should be ensured through appropriate institutional support and awareness raising. Panchayati Raj Institutions should be suitably strengthened to mobilize local communities to lead the conservation and utilization. Gene sanctuaries for selected species, using participatory, IK and TK and scientific approaches, should be established
and judiciously managed. The local communities should be a partner in the conservation process and duly compensated.

4.1.5.55 Hill farmers traditional practices unfold significant knowledge and information about the multiple roles of biodiversity and agro-biodiversity in using marginal lands productivity and livelihood security. The indigenous and traditional knowledge systems should be duly protected under the PPVFR. The Village Knowledge Centres should actively promote gene literacy.

Diversification for Enhanced and Congruent Economic, Employment and Ecological Security

4.1.5.56 The farming-based livelihoods in the Himalayas today present a landscape of scenarios, ranging from total diversification and better off farming communities to still continuing subsistence farming, poverty and extreme distress situations of unsustainable farming and livelihood conditions. Lessons of the experiences indicate that besides several other options, such as generating non-farm employment opportunities through infrastructure development for tourism etc, farming will remain the basis for alleviating poverty of the most distressed farming communities. Priority focus on most distressed class of hill farmers is emphasized to avoid further alienation and disparities which are becoming wider. Thus, the next round of hill agriculture diversification interventions (such as the horticulture mission) need to aim at new set of thrusts to synergistically integrate economics, employment and ecology over wide range of farming conditions by forging backward linkages to agrobiodiversity / biodiversity and local people and forward linkages with agroprocessing, agribusiness and marketing.

4.1.5.57 At national level there has been a general lack of recognition of the niches that hilly and mountain areas offer to increase income generation opportunities without any serious damage to environment. Therefore, there has been lack of appropriate policies to promote such activities. Much efforts are needed to identify the dormant niches of hill agriculture across the Himalayas. The production niches and biodiversity have potentials to convert marginal uplands and water bodies into productive production systems. There are areas in the Himalayan region that in fact have a significant potential
for research-driven productivity increases, and that the returns on investment in these areas may even surpass favoured areas in the plains. Agroforestry involving high value species such as *Arjun* trees for *Tasar* silk production, Jatropa and other fuel trees, oil-bearing trees and bushes, such as olives in J&K, nitrogen fixing fertilizer trees and other soil health enhancing trees should be promoted in so called degraded lands. Only proven genetically superior planting materials should be used for these plantations. Similar opportunities exist for livestock and fisheries, in solo and/or integrated crop-horticulture-agroforestry-livestock-fisheries farming systems.

4.1.5.58 **Horticulture-led transformation:** While there will not be any dispute on priority to horticulture, the choice of most appropriate crops should get priority attention. The Himalayan farmers will need a range of horticulture crops to be able to satisfy all kinds of needs, namely, agro-ecological niches, farmland types and socio-economic settings. The well known fruit crops i.e. apples, plums, peaches, pears, oranges, walnuts, kiwi, cherry, etc form one group of developed hybrid crops. In some States, however, there is high concentration of one or two fruit crops, which may not be advisable in the long run. For instance, in Himachal Pradesh, apple accounts for over 70 percent of the fruit production, although the apple yield and quality (of certain production systems) are not upto the mark, let alone the neglect of other equally or more promising fruit and even major food security crops. Several other States have also tried to replicate the Himachal’s experience but with less than desired outcome. Despite the increased population and distribution of domestic apples, in the post-WTO regime, import of apple from China, Australia and New Zealand is swelling fast because of superior quality and competitive prices. The various apple producing hill States should identify quality varieties most suited to their niches and their production peaks noncoinciding with the peaks in other States to ensure remunerative returns to the growers and prolonged availability of quality apple to the consumers.

4.1.5.59 The Himalayan farmlands and farmers also hold very special niches for other lesser known but native / indigenous horticulture crops, which if promoted will provide exclusive comparative advantage over markets and ecological suitability. Based on market research and agro-ecological mapping and matching, through inter-State
consultation, commercial production and distribution of selected priority species should be systematically undertaken by commodity-specific SHGs or SFEs or through contract farming. High value crops like saffron and *Kala Zeera*, with due R & D support, can prove much more remunerative. Besides the major temperate fruits like apple, pear, walnut, seabuckthorn in cold arid zone, cardamom in Sikkim, organic tea in SFEs of Assam, passion fruit in Mizoram, Sikkim, Nagaland and Arunachal Pradesh, ginger and turmeric in Meghalaya and Mizoram, deserve high priority. Considering profitability, low perishability and ecological compatibility, **greater attention should be paid to the production and marketing of fruit nuts** viz. walnut, pecan and hazelnut. Anthuriums and orchids, through group farming and marketing, could become major commercial enterprises in the Himalayas. The Land Use Boards, NHM and NHB and the proposed National Hill Coordinating Centre should play a proactive role in delineation of production regimes and promotion of marketing to create win-win situation for all the partners.

4.1.5.60 Diversification of hill farming to medicinal and aromatic plants has a distinct advantage, but has remained largely underexploited and unorganized. However, so far the opportunity remains locked up for the hill farmers in the institutional framework. Steps require revisiting sensitive issues of conservation, restricting rights to wild harvesting, removing restrictions on marketing of cultivated produce rather making farming more remunerative, and even enhancing access to land resources to particular ethnic communities. A separate **National Mission on Medicinal and Aromatic Plants (NMMAP)** should be established (see First Report and Chapter 4.5 of this Report).

4.1.5.61 Sustainable economic activities, proven technological interventions, timely institutional support and effective partnerships (public-private partnership) should fortify ecological – economic interactions and interdependence. Greater emphasis should be placed on strengthening the links between the producer, the industry and the consumer. Grassroot institutions, including SHGs and cooperatives, should be established and suitably empowered by financial assistance, information flow and skill development for strengthening production–post harvest handling–processing–value
addition--marketing chain. Good experiences of NDDB and sugarcane cooperatives in Maharashtra should be widely shared. Panchayati Raj Institutions should play a leading role especially in mobilizing community actions for conservation and improvement of natural resource base. SMEs should be supported, including through enhancing their access to adequate formal credit, to establish and effectively run agribusinesses in rural areas. Income enhancement and profit margins of farmers, especially of small and marginal farmers, should be a major consideration along with ecological security concerns. The successful experiences of one hill State could be easily replicated in another hill State. Creation of clientele clusters with integration of production – processing - marketing, as practiced for apple in Himachal, will be helpful in generating meaningful employment and retaining the Uttarakhand males in their villages linked with their lands and families rather than migrating to cities in large numbers. It is proposed to train 300,000 farmers and 500 trainers at various levels in specialized areas to promote production, processing and marketing of the priority species.

4.1.5.62 New crops from the Himalayan wild biodiversity constitute the greatest strength of the medicinal plants farming sector. These are wild plants most suited to the local environment and qualify as new crops without years of scientific inputs to convert them into cultivated crops. It is revolution of a kind for creating new cash crops, most suited to hills and not thought of in the food sector. The wild source factor also holds the key to niche and comparative advantage. This sector is highly significant from the angle of both national strategic interests of conservation and local economic needs. Identifying and developing backward and forward linkages for these new crops of the Himalayas will need to be worked out before putting them on promotion path, especially keeping in view the interest of the smallholders.

4.1.5.63 We also need new generation of institutional support for this sector to succeed. For instance, the Institute of Himalayan Bioresources Technology (IHBT), Palampur, Himachal Pradesh, which is working on developing the whole chain---identifying the source of new crop from the wild, to developing cultivation protocols, to post harvest processing including the prototypes of machines for each household or
village scale to market linkages, the complete solution package. The IHBT is a rare example of new generation institutions with whole range of new crops of this category from the NW Himalayas waiting to be harnessed for the benefit of the Himalayan farmers. IHBT also provides the clue as to what kind of institutions are needed and as to what should be the strategy to restructure and reform research and extension institutions to enhance their excellence, relevance and responsiveness to the dynamic national and international agricultural and trade scenarios.

4.1.5.64 **Integration of livestock for livelihood security:** Livestock has been the basis of subsistence livelihood of the hill farmers. It has potential to transform into one of the most viable options of agricultural diversification, along with horticulture. Unfortunately, some of the practices such as nomadism, bakarwals and Gujjars’ buffalo herds have been facing stiff regulatory controls and find it hard to continue any longer—the distress calls from them are for real. Livestock based livelihood options of these most marginalized and underprivileged people should be seen in right perspective so that regulatory mechanisms are modified to the extent that the farmers are saved from abandoning these options. In view of the increasing domestic demand and export potential for meat, the national capacity should be strengthened for hygienic production, processing and marketing of meat. In some of the hill States, such as Jammu and Kashmir, there is serious shortage of meat, which could be mitigated by rearing of more efficient meat producing animals such as rabbits, lamas and alpacas.

4.1.5.65 Along with the use of most promising and adapted breeds, modern diagnostic and disease management, priority support is needed to reduce acute fodder scarcity and to ensure feed and nutritional security of livestock. Both productive grazing lands and fodder for stall feeding need attention. While the alien invasive weed species should be completely weeded out, quarantine measures should be strictly adhered to avoid further infestation as well as good grazing practices should be enforced. Each State should establish **State Livestock Food Corporation** for comprehensively addressing the livestock nutrition problem. To begin with, in line with the proposed Livestock Food Corporation of India (see Chapter 10 of the First Report). SHG-based 1,000 fodder and
feed banks should be strategically located and supported both by public and private financial and service centres

4.1.5.66 Fisheries for nutritional and income adequacy: Science-based integrated fisheries development in the hills can greatly help in bridging the nutritional and income gaps. The NER States should strengthen their capacities to harness their huge fisheries, production, potential, thus minimise their daily costly imports from distant places in the country. Development of markets, especially export markets, through the creation or expansion of Export Zones, for speciality fishes is essential for stimulating domestic distribution as well as exports. SPS and TBT concerns must be addressed effectively to realize gains from the technological advances in fisheries product diversification and value addition, which should be supported also by appropriate fiscal and regulatory policies. Concerted effort is needed to eliminate fish diseases, particularly in the coldwater fishes. Vigorous efforts will be needed to educate producers, processors and exporters in clean and safe production. The private sector is also showing great interest in promoting fisheries in the hills but this must be done with care keeping in mind the equity and environmental sustainability considerations. Necessary research, extension and training back-up is essential to harness the potential (see Chapter 3).

Organic Farming: More of a Necessity and Less of a Choice

4.1.5.67 Organic farming is ideally suited to hill agriculture, especially for MAP and horticultural species and to jhuming. Uttarakhal leads the Himalayan States in adopting organic farming for harnessing the ecology-economics synergy and has declared itself as an Organic State (Box 6). Himachal Pradesh, Sikkim, Nagaland and Manipur have also taken several steps towards mainstreaming organic farming.

4.1.5.68 Around 50 tonnes of different varieties of organic spices were produced annually under the auspices of the Spices Board which has formulated well-developed protocols for organic production of spice crops, their certification system and market links. To begin with, the hill States should concentrate on production of organic spices (ginger, turmeric, black pepper, large cardamom) and different medicinal and aromatic
plants. Assuming that a market growth of organic spices in Europe, US and Japan is approximately 10% per annum, export of organic spice will get a significant production boost in the coming years. Same is the case of organic tea, where international demand is very high and smallholders’ organic tea gardens promise high socio-economic returns. About 25,000 model Organic Villages or contract farms of the strategic commodities should be developed in the hills during the next seven years.

Box 6

Uttaranchal: an Organic State

Organic Farming is identified as sine qua non for mountain farming in the State

The three pronged strategy comprises of:
- Dissemination of suitable technology.
- Development of appropriate certification regime.
- Building marketing networks.

Institutional framework put in place
- Uttarakhal Organic Commodities Board established in 2003.
- Three Centres of Excellence opened in 2003.
- Uttarakhal Seeds and Organic Produce Certification Agency came into being in 2003 which is first such agency to obtain ISO9001:2000 and ISO 65 accreditation from DET NORKSE VERITAS of Netherlands.

Multi agency extension approach adopted
The extension agencies are:
- Grass root level para workers
- Self Help Groups/Farmers Interest Groups
- Agripreneurs/Agriclinicians
- Department of Agriculture

New Concepts evolved and translated into practice successfully
- Model bio-villages (1200 in number covering 20000 farmers/19000 hectares)
- Convergence of pre-harvest and post-harvest practices at farm/village level
- Finger Millets hitherto the most neglected crop now mainstreamed in export quality baby food (Now being exported to Japan/procured for ICDS programme)

Long Term Agenda
- Mapping, in situ conservation and propagation of crop bio diversity
- Integration of ITK in development of package of agronomic practices
- Building a Brand Equity for Uttarakhal products
- Exploring new income generation with outreach programmes
- Networking with other mountain States and working as role model.
Although the GOI has already taken steps to have indigenous certification system to help small and marginal growers and to issue valid organic certificates through certifying agencies accredited by APEDA / Coffee Board / Tea Board / Spices Board, the situation is far from satisfactory. A focused national movement on organic agriculture with a credible certification of the process and produce, coupled with quality and trade awareness and literacy is a sine qua non for mainstreaming and integrating organic farming in the national agricultural economy. It must be emphasized that establishing and running credible organic farming systems is much more complex and demanding than the usual inorganic-based agriculture. But, it is do-able and should be done for harnessing the unique opportunities in India and abroad.

Debate on institutional back up support for organic farming to succeed in the hills should be widened and intensified. R&D institutions are still very weak and States will need to work out policies providing enabling environment for promoting organic farming. Also organic agriculture research and technology generation is changing the whole concept of innovators. So far in India farmers have become leaders in innovations and scientific fraternity is looking from the sides. Much of the Green Revolution technology protocols, methodologies and perspectives, to which scientists are used to, are inappropriate for organic agriculture. Organic agriculture may also lead to farmer scientist partnership and real on-farm technology development and refinement. Organic agriculture is about following ecological principles in farming and its technological options are therefore sensitive to ecological conditions of a farm. This implies that outside technological solutions will always take second place to on-farm innovations, contrary to conventional Green Revolution technological practices.

In an estimated US $ 30 billion global market of organic products, India’s share is hardly 0.1%, the huge potential notwithstanding. The wide gap is due to poor market research, the lack of certification capacity to ensure quality and brand labelling and the lack of research and development support, including an effective monitoring and technology transfer system. The Ministry of Agriculture, alongwith NABARD, should urgently bridge this gap by initiating the much-needed market and policy research. The National Programme for Organic Production (NPOP) having
internationally agreed standards for products and labelling as India Organic was started in May 2000. The hill States should not only be linked with the NPOP, but should be given priority because of the obvious comparative advantages.

**Reorientation of Research, Technology Development and Extension and Harnessing of Group Dynamics**

4.1.5.72 Agricultural development in the hills should become a knowledge intensive business. Right niche identification, technological support and access to institutional support are the important factors affecting the level of transformation of hill farming. The lack of skilled agricultural work force and poor technology transfer mechanisms in most hill States emphasises the urgent need for a strong technology policy in each State and revamping of the research and extension systems.

4.1.5.73 Productivity of hill agriculture is comparatively low and is declining. Greater attention is therefore needed to alleviate the constraints by synergizing economic and ecological values, sometimes promoting services and programmes which bring better economic value even at lower productivity. **Genetically improved strains combining productivity, quality and resistance to biotic and abiotic stresses, IPM and IPNS evolved through farmers’ participation should be the pith of the technology packages. Farmer Participatory Research and Knowledge Management Systems should be used for harnessing the rich indigenous genetic heterogeneity for optimizing the benefits of agro-ecological and socio-cultural variability, such as the development of New Hill Rices. Post harvest primary processing, value addition (reducing volume and increasing value) and prevention of post harvest losses by establishing appropriate backward and forward linkages is another priority area awaiting concerted attention and effort.** The status of agro-based industries in the Himalayas is not very satisfactory despite high potential. **The KVKs and ATMA should include strong components of trainings on value addition, rural processing and marketing, and should be restructured accordingly.**
4.1.5.74 Hills being inherently marginal in terms of their natural endowment, simple talk of improving productivity and production of conventional crops and systems prevalent in the plains will not be of much help in the hills. Several public sector Institutes, Universities, coupled with the State Governments’ research and technology development institutions have evolved technologies but there is a serious gap in diffusion and adoption of the technologies. There is a need for reskilling and retooling research and extension personnel. Alternative extension tools, such as farmer to farmer extension, market-led extension, producer-consumer partnership will need to be refined and popularized. Over 10,000 farm schools should be established during the next seven Years. The integrated farming system strategy for hills need to be revisited and fine-tuned to capture the location-specific needs and opportunities The recommendations made by the Swaminathan Committee for strengthening research, technology and human resources development in the North Eastern region, especially the setting up of a separate cadre of agriculture researchers should be adopted and implemented without delay.

4.1.5.75 Skill upgradation and capacity building of tribal farmers through intensive training should be seen as the first step before taking up programmes like area expansion of new crops. A structured two-tier training programme needs to be institutionalised. Firstly, the departmental experts and extension agents should be trained by R & D Staff. Secondly, the advanced technologies need to be demonstrated in farmers’ fields on selected basis involving the local R & D institutions. A paradigm shift from unskilled to skilled work and enhancing access to quality (sanitary and phytosanitary measures) and trade (quality, price, market, etc) literacy with reference to home and external markets are essential.

4.1.5.76 The Agro-horti-silvi-pastoral system developed by ICAR has been identified as economically viable, eco-friendly and sustainable land use system for the NEH region. Technology transfer for valleys and plains has taken place to a limited extent but the models suggested as alternates to Jhuming have not been replicated and adopted. Similarly, the package of practices for rejuvenation of declined orange orchards developed by ICAR have not spread extensively. Such technology transfer gaps should
be analysed and their redressal mechanism found in a participatory mode by creating a consortium involving the ICAR institutes, SAUs, other Universities, private sector, NGOs and farmers.

4.1.5.77 **Farming has to become knowledge intensive** if it is to become competitive for which retooling and retraining of extension personnel and establishment of rural knowledge centres are essential. For remote tribal areas groups extension through formation of SHGs is perhaps the best option and it should be easier to organize training of the members of the SHGs. This process empowers the poor and enables them to control direction of own development by identifying their felt needs. Assam has some experience in formation of SHGs and channelling micro-finance through these Groups. Group approach to extension through SHG should aim improvement of agricultural production system of the niche crops and associated support services such as marketing, primary processing and reduction of post harvest losses. The small farmers SHGs should be helped to organize establishment of Small Farmers Estates (SFE) covering an area of 100-200 ha each to capture the economies of scale. It is proposed to establish 25,000 SFEs in hill area during the next seven years.

**Supply of Quality Planting Materials and other Inputs**

4.1.5.78 Inferior and spurious input supply, specially poor quality seeds and planting materials, fertilizers and pesticides, is a common issue of hill farmers across the Himalayan States. Much needs to be done in this area. One of the main reasons for stagnating yields and low productivity of apple orchards in Himachal Pradesh and Uttarakhand has been the poor planting materials used in the past and non-availability of quality materials for new and replantings. Therefore, it is suggested that as the highest priority, the public as well as the private sectors should join hands in establishing and maintaining quality mother plant nurseries both for root stocks and desired scion materials. State Plans for flow of quality planting materials of apples and other priority crops should be number one priority of Himachal Pradesh and Uttaranchal. The recently launched National Horticulture Mission should, in close consultation with the stakeholders, allocate desired financial and technical supports to this most critical area.
4.1.5.79 Although seed production and distribution should primarily be in hands of (enlightened) private sector, there are certain “orphan” commodities and geographic areas where effective leadership and indulgence of the public sector and public-private partnership is essential. In a public-private partnership mode, as beginning to happen in some of the hill States, Seed Villages, Horticulture and Plantation Crop Rural Nurseries, Seed and Planting Material Self Help Groups, especially Women Self Help Groups, should be organized and supported. At least 30,00 such units should be established and should constitute the national grid of certified mother nurseries. Their stocks should be inventorised and the list should be available for general use. Incentives should be provided to the private sector atleast in the early stages. Individual institutions, Universities - public or private, and Government Departments should be responsible and duly empowered to timely supply breeder and mother planting materials and foundation seeds. Each State should develop annual plan for timely, quality adequate and rationally priced production and distribution of seeds and other planting materials and should have a credible system of monitoring and correcting the unhindered flow of quality seed from the breeder/originator to the farmers.

Credit and other Institutional Support

4.1.5.80 In general, access to finance and cheaper credit have not helped hill farmers. Banks favour credit to those who can generate surplus and to small scale enterprises for cost effectiveness and profitability, rather than to small and marginal hill farmers. Average credit received by a hill farmer is 40 percent of that received by his counterpart in the plains. As mentioned earlier, NABARD and other banks have come up with credit packages specifically designed for hill farmers, but the actual delivery is dismal. Infact, the formal credit squeeze upon hill agriculture is presently acute. It may mean revival of private money-lending in hilly areas. The credit regulations are not in conformity with the land tenure systems of NE and therefore the most needy tribal farmers and women-headed households have never been able to benefit from the credit system. The Kisan Credit Cards scheme has helped only a handful of farmers, and
the women farmers and women-headed households have generally been left out. The issues of land rights and credit access should be addressed urgently.

4.1.5.81 Service costs and creation of infrastructure, such as constructing an irrigation device or facility are costlier in hills than in the plains. These differences should be considered while deciding the credit level. Credit should also support SMEs to also strengthen marketing, storage and value addition chains. New innovations are needed in credit and finance system to make the products pro-small and pro-marginal hill farmers. Small farmers have small surpluses for market and that is not seen as viable opportunity by credit and finance systems. Keeping in mind the problems of hill farmers, attitude of the credit institutions towards the poor will need to be adjusted. The public sector should assist the banks in covering their undue risks in hill areas and in designing and delivering credit products suitable for hill farmers. Insurance coverage of the hill farmer is almost negligible. Special insurance products and dispensation mechanism, duly supported by the Central Government, will be needed.

4.1.5.82 As mentioned earlier, NER has been receiving liberal financial assistance and special schemes for promotion of horticulture and overall agriculture through GOI funded projects and supports of other financial institutions. Shyness of the people, lack of skilled agricultural workforce, inappropriate land tenure system and ineffective governance are some of the socio-cultural constraints coming in the way of proper utilization of funds. The apathy of State Governments towards investing in agriculture-led development notwithstanding, the absence of private sector participation in the developmental process has also hampered growth of institutional support in the hills. Land reforms and institutional reforms are interlinked with institutional support and therefore cannot be overlooked. The flow of credit and other financial supports to farmers in the NWR have not been as good as in the NER. Suitable institutional arrangements are needed to reduce this disparity. As noted in Section 3, NABARD, NEFDi and SCBs have several schemes to support hill farmers. But, their impact is localized and limited, and often short-lived. The Programmes should be critically evaluated and successful ones should be widely replicated. Lessons should also be learnt
from failed cases both for correcting and resurrecting the past mistakes and for avoiding the future pitfalls.

Central Place of Women in Hill Agriculture

4.1.5.83 Mountain women have traditionally been the invisible work force, the less acknowledged backbone of the family economy. In the hills, whether the men are in the household or have migrated elsewhere to supplement the family livelihood needs, the women have their major share of duties. Looking more closely at the type of work that women do, we can distinguish three main areas, all crucial to keeping the family and indeed the hill economy alive. These three areas are: survival tasks, work in the households and income generation.

4.1.5.84 In particular, hill women have been contributing substantially to the family budget through income generating activities. This is particularly the case for the growing number of female-headed households where men have to migrate in search of work. Even where a woman is not completely alone, contribution of women to the household budget is of utmost importance to the family, more so because women spend more of their income on family welfare. However, even though, women fulfil a great number of essential tasks, they have limited access to and control over income, credit, land, education, training and information. Further, hill women are not only the most important food producers, but are also custodians of rich traditional knowledge of farming practices, food, fuel, feed, fiber and medicinal values and uses of local and indigenous bioresources.

4.1.5.85 It is only recently that participation of women in development programs in hilly areas is being considered necessary. The extension approaches and tools may still be gender biased and therefore much needs to be done to encourage cooperation and partnership of women in hill development. The recent successful experiences with Mahila Mandals and SHGs in several hilly States is a reminder of the potential of partnership of women in hilly areas development. Women empowerment, as envisaged in the “New Deal for Women in Agriculture” (Chapter 4, First Report, NCF), assumes extremely high
priority in hill agriculture, especially enhanced access of hill women to land rights, credit, insurance, education, technology (drudgery-reducing tools and implements), training and skill development and information.

Completing the Unfinished Land Reforms

4.1.5.86 Traditionally, community ownership of land is prevalent in hill tribal communities, especially in the NER. Valley lands, terraced land, homestead land, short fallow lands are normally recognized as private lands for all practical purposes. Better productivity and higher economic returns from such privately owned land provide incentives for crop diversification and commercial horticulture. The prevalent land tenure system in Hill districts and absence of land records and legalized ownership rights hamper technology adoption, investment in land care and sustainability and the flow of bank credit. Land in the hills under shifting (Jhum) cultivation is essentially community land. The Jhuming cycle is getting reduced because of population pressure. If ownership rights on part of the community land presently under the Jhuming can be given, perennial horticultural crops can come up well as a viable alternative. The data on land utilization pattern in N.E.H. Region show that about 60% of the area is under forest and only 17.5% of the Jhum land comes under cultivation at one point of time. It is thus apparent that large part of the landed area in the region remains unutilized every year and expansion under seasonal horticultural crops including MAP should not therefore be constrained for want of land. The Village Knowledge Centres could be entrusted to prepare land records.

Marketing for Enhancing Farmers’ Income and Welfare

4.1.5.87 Farmer-centric marketing and pricing system is the most important factor in agriculture-led socio-economic and livelihood enhancement. An efficient agricultural marketing system is essential for the development of the agricultural sector and for providing incentives to the farmers for increasing production and also for commercialization of agriculture. In hills and mountains, the production-distribution
disconnect is very wide. For instance, in the entire Kashmir Valley and Ladakh, there is no foodgrain market.

4.1.5.88 Inaccessibility and high transport, packaging and storage costs result in unlevelled playing fields for hill farmers in securing remunerative returns for their produces. Therefore, development and use of necessary marketing infrastructures, rural warehouses, roads, market yards (mandis), cool chains, **transport and storages in hills should be subsidized to enhance pricing parity**. With increasing diversification of hill agriculture towards horticultural, plantation and medicinal and aromatic plants, the hill farmers will increasingly be trading high proportions of perishable commodities. The HPMC model of apple trading, the NERAMAC for horticultural products trading in the NER, the HOPCOM system of Bangalore, the NDDB marketing network for dairy *plus* horticultural products in various parts of the country alongwith Azadpur Mandi of Delhi have been operational for quite some time with varying successes. While the NDDB model has been most successful, the other models require significant improvement. The APMC reforms and the new Act including contract farming and creation of a Common Indian Market, are expected to suitably strengthen the producer-consumer and end-to-end linkages value addition for and to promote integrated use of processing facilities. Minimum Price Support and Insurance should greatly help the hill farmers and strengthen the agro industries partnerships.

4.1.5.89 Monopolistic practices and modalities have come in the way of free and competitive trade in agriculture-marketing, futures markets, use of latest technologies in post harvest technology, handling of exports, agro-based industries, warehousings, etc. There is also a need for downsizing the distribution chain and helping the farmers to get the better of the consumer price. Rural godowns to prevent distress sales, market exploitation and storage losses should be established. This is crucial. Then, there is also a question of huge infrastructural investments for modernizing our marketing systems. An Expert Committee set up by the Ministry of Agriculture had estimated that an investment of Rs 11, 172 crore in next 10 years would be necessary for infrastructural development for agriculture marketing. It would be reasonable to expect that a substantial part of this
investment may have to come from the private sector. Given the prevailing poor connectivity and highly inadequate market infrastructures in the hills, the hill States should receive relatively higher proportion of the proposed investment, say at least, 40 percent, that is, nearly Rs 300 crores during the next seven years.

4.1.5.90 The draft model APMC Act stipulates reforms to promote competitive markets in private and cooperative sector, to encourage direct marketing and contract farming, to facilitate industries and large trading companies to undertake procurement of agricultural produce directly from the growers and to eventually establish linkages between the producers and the consumers. Some of the States, especially the NWR States, have adopted the revised APMC Act, the remaining States should hasten the process. Support for infrastructures, including information system and for trained human resources should urgently be provided. Quality, biosafety and trade literacy of farmers and others in the production – processing – marketing chain should be improved.

4.1.5.91 Fortunately, for hill States, the NHM has substantial funds, including those for marketing, and post harvest development. But, these funds have so far not been used suitably. The National Director of the NHM should give highest priority to the marketing components rather than to disbursement of subsidies for new planting and production programmes. If necessary, within the overall provision under NHM, and also coordinating with other ongoing or planned projects, desired funds should be mobilized to adequately support the marketing modernization plans in the hills.

4.1.5.92 Space distribution of periodic markets and exploitation by the vested groups in the marketing sector are special features in the hills. Sale to pre-harvest contractors also prevail in certain areas. The marketing system is totally outdated and only a handful of traders cover most of the nearby markets which are essentially ‘buyers markets’. Private markets are yet to establish themselves at the areas of production. Due to thin spread of primary markets, the growers normally have to trek a long distance to bring the farm produce and normally sell the produce to the middlemen at a price dictated by them. Although, under the new APMC Act, the private sector is expected to invest in marketing infrastructures, but this may not happen for a long time in the often isolated
difficult-to-access mountain villages, resulting in widening of the socio-economic divides. **To bridge the divide and also to attract private sector investment, the public sector must invest initially in establishing rural market yards and collection points.** Such initiatives will also promote contract farming involving hitherto unreached farmers. **Bio-parks** on major commodities and **Food Parks** should be established by concerned Ministries to promote value-addition, product diversification and total bio-mass utilization.

4.1.5.93 In reality, modern marketing system for the horticultural commodity does not exist in the hills. The new concept of marketing which includes post-harvest handling, assembly, transport, storage, credit, packing and processing is not very easily achievable in the hilly terrains. The communication and transport system is weakly developed as a result of which very often market glut is experienced. In case of fruits like pineappple, where fruits can be harvested only at full maturity and the fruit is highly perishable and spoilage is very high, there is no integration of marketing of horticulture produce from hills to other parts of the country. Illegal trade of fruits and vegetables with Bangladesh and Myanmar is reported to be going on a substantial scale. Legislation of trade for perishable horticultural commodities with the adjoining countries, particularly Bangladesh, should be able to help in establishing markets in the border areas of most of the NER States for legal trading.

4.1.5.94 Keeping in view the difficult marketing and processing situation in the NER, the Government of India had set up the North Eastern Regional Agricultural Marketing Corporation (NERAMAC) in 1982. The major objectives of NERAMAC was to organise and promote marketing of major agri-horticultual produce and processed product in the region. The corporation has set up a big Fruit Juice Concentrate (FJC) plant in Nalkata in Tripura, a cashewnut processing unit at Agartala, and has opened a few retail outlets and Kiosks. NERAMAC is promoting procurement and marketing of horticultural produce and products to a limited scale. The presence of NERAMAC in marketing is still very negligible and it has to go a long way to make its presence felt for bringing significant improvement in the marketing sector. Under HTM, there is a provision to establish 29 whole sale markets, 199 rural primary markets, 26 Apni Mandis,
and 15 grading laboratories for mitigating the problems of marketing of horticulture produce. Also, NEDFi has established a buyer-seller platform in Guwahati. Such initiatives should be operationalised soonest to help improve income of the hill farmer.

4.1.5.95 As no market functions in isolation, isolated markets taken up for development may not be individually important but being collectively inter-linked make a significant contribution to a given commodity or a group of commodities. Thus, separate Regional Master Plans for Market Development should be prepared for the NWR and NER. This could serve as a bankable document assessing the State-wise development requirements, phasing out of programmes, indicating State-wise as well as regional order of priority for development, developing a regional commodity map, estimating market space requirement at different locations in different States, framing cost estimates and modernization proposal with strengthening legal and conceptual framework. Further, a campaign can be launched for development of Rural Periodic Markets (RPMs), Seasonal Markets, Daily markets and PRIs controlled markets preferably through the National Horticulture Mission. The NER could be integrated with South and South East Asian economy for converting the remote and isolated NER into the main route for trade and economic linkage of mainland India with South and S.E. Asia. Likewise, the NWR would be connected with the Near East Asian and North West African countries and with the European common market.

4.1.5.96 Finally, the power of scale in production–marketing chain must be harnessed. Specialised marketing SHGs, SFEs and marketing cooperatives should be promoted to undertake Group Marketing, linking the produce directly with the consumer (buyer). The Micro-capital Grant (MCG) support for post harvest management should be integrated with production practice and community based post harvest management facilities and through farmers training on marketing and awareness about price differential on quality, intra and inter seasonal price difference and market to market price difference. The trained marketing groups should be encouraged to avail MCG support for improved marketing of local produce. Seasonal storage as a marketing function for off-seasonal selling could very well be organized with little capital support.
4.1.6.0 Resource Allocation

4.1.6.1 Additional resources are sought for the remaining two years of the present Plan and the five years of the 11th Plan in the areas of resource management, namely, water security, soil health, biodiversity conservation and sharing; special institutional support (credit, insurance and life-saving catalytic interventions); human capital build-up to create skilled and trained human power and empowerment of farming and rural communities such as SHGs and SFEs and gender mainstreaming; services support through strengthened research, technology and extension mechanisms, including policy, management and marketing research towards need and knowledge-based policy changes, adequate and timely availability of quality planting materials; and market infrastructural development.

4.1.6.2 Investments are needed for creating and managing network of water harvesting and efficient water distribution and utilization system in the present and immediate future and a long-term strategy and programme for maintaining hydrological balance in the Himalayas. Factor-oriented (eg. micronutrient deficiencies, agricultural implements, etc) and system-oriented (crop-livestock-tree integration) demonstrations are needed through the mobilization of group power and dynamism by establishment and empowerment of SHGs, SFEs, etc. for integrating production, processing and marketing and creation of non-farm employment. Farm schools, mother nurseries and an effective system for ensuring timely flow of quality seed and planting materials especially for converting marginal and degraded lands into lands of opportunities, production and marketing of certified high quality organic products, including “doubly green” herbal medicinal and aromatic products, will need substantial additional resource allocations. Food, fodder/forage, seed and water banks are required for achieving food, nutritional and clean drinking water security.

4.1.6.3 An additional sum of Rs 2,265 crores, as detailed below, may be provided during the next seven years to cater to the above requirements:
<table>
<thead>
<tr>
<th>Sl. No.</th>
<th>Requirements for the next five years</th>
<th>Rs., in crores</th>
</tr>
</thead>
<tbody>
<tr>
<td>(i)</td>
<td>Water conservation tanks with and without distribution attachments @ Rs 17,000 without attachment and Rs 45,000 with attachment to be provided in the North-West and North-Eastern hill States, in the first phase covering only 50% of the requirement.</td>
<td>365.00</td>
</tr>
<tr>
<td>(ii)</td>
<td>Support to micro-irrigation, establishment and operation of water user associations, repair and maintenance of degraded irrigation systems, expansion of lift irrigation, development and promotion of suitable machines and implements to reduce drudgery and improve efficiency.</td>
<td>300.00</td>
</tr>
<tr>
<td>(iii)</td>
<td>Establishment and operation of National Centre on Glacierology</td>
<td>50.00</td>
</tr>
<tr>
<td>(iv)</td>
<td>Support to special credit and insurance products and provisions for transport subsidy for improvement of marketing cost parity</td>
<td>500.00</td>
</tr>
<tr>
<td>(v)</td>
<td>Marketing infrastructural development</td>
<td>300.00</td>
</tr>
<tr>
<td>(vi)</td>
<td>Promotion of organic products particularly for export markets through creation of credible certification system and establishment of 25,000 model organic villages/contract farms (to be partly supported by the Centre).</td>
<td>250.00</td>
</tr>
<tr>
<td>(vii)</td>
<td>Capacity building through training of 30,000 farmers, 500 trainers and development officials in specialized areas, creation of and support to 10,000 Farm Schools, Small Farmers Estates (10,000) and Self Help Groups (20,000), establishment and operation of foodgrains, fodder and seed banks, soil testing laboratories for micronutrients and strengthening of Village Knowledge Centre for digitizing land records, etc and promotion of production and distribution of quality planting materials by establishing 30,000 units throughout the hill zones.</td>
<td>500.00</td>
</tr>
<tr>
<td></td>
<td><strong>Grand total</strong></td>
<td><strong>Rs 2265.00</strong></td>
</tr>
</tbody>
</table>

4.1.6.4 Adequate financial and human resources should be made available to undertake in-depth studies on: (i) the interactions and implications of hydrological
processes, biological productivity, sustainability and climate change, (ii) interrelationships of forest conservation and protection, agricultural production, income, floods, lowland-upland linkages and integration of watersheds with river basins, (iii) land area delineation based on usual geographic surveys measuring only horizontal area and Sat- and GIS-based survey accounting for slopes and implications of the discrepancy between the two measurements, (iv) prospects of organic farming for harnessing unique agro-ecological settings of hills and mountains and the new export market opportunities, and (v) scope and mechanism of implementation of PVPFR Act and realization of farmers’ and communities’ rights and development of environmental indicators and their use in enhancing ecological sustainability and equity.

4.1.6.5 The inherent handicaps of inaccessibility, marginality, fragility and higher costs (as compared to plains) of product development, marketing, transport and service provisions, as well as the unique opportunities, should be kept in mind while making the allocations. The Central Government have been investing substantially in NER and the Planning Commission-managed Hill, Western Ghats, Eastern Ghats, Deccan Plateau and Border Area Development Programmes, but in a diffused and thinly distributed manner, resulting in poor outcomes and impacts. Focussed priority-based reallocations with clear-cut responsibility, authority and accountability is a must.

4.1.6.6 Horticulture-led diversification under the National Horticulture Mission should emphasise prevention of post-harvest losses, processing, value addition, cool chains and marketing and not subsidy-induced area expansion. Part of the investment in improving water conservation and recycling should be made from the multi-Ministry supported watershed projects in the country. As regards transfer of proven technologies through large-scale demonstrations, funds could be reallocated from the ongoing Mission Mode programmes. Part of the investments of the Ministry of Environment and Forests and the Ministry of Health related to biodiversity conservation and improvement of medicinal and aromatic plants as well as organic agriculture, should be diverted to meet the activities suggested in this Report.
4.1.6.7 In order to cater to the specialized needs of hill agriculture, the ICAR should allocate part of its resources for technology generation refinements and adoption and extension activities. The Council should establish a branch of the Central Arid Zone Research Institute (Jodhpur) in Ladakh to cater to the needs of cold arid agro eco-systems in the high mountains. The efforts of a consortium of institutions related with hill agriculture and mountain development comprising ICAR, CSIR and DRDO as well as agriculture and non-agriculture Universities in the Hills, in association with the International Centre for Integrated Mountain Development (ICIMOD), should be synergized through the proposed National Programme on Hill and Mountain Agro Ecosystem. Actually, often it is not the problem of paucity of funds but it is the problem of non-judicious and poorly-coordinated utilization of the resources, which must be rectified urgently.

Acknowledgement

This Report is based on extensive consultations at various levels and several desk studies. In particular, the National Commission on Farmers is indebted to the ICAR especially the nodal agency ICAR Research Complex for NEH Region, for organizing the Experts Consultation on North East Region Hill Agriculture on the 26th and 27th April, 2005 at Barapani. The Commission is also grateful to all the North Eastern State Governments, including Sikkim, and in particular the host Meghalaya, for deputing their experts and farmers of the States. The Commission also thanks the banks and financial institutions, ICAR Institutions, State Agricultural Universities, NGOs, SHGs, Cooperatives, industries, etc., for their active participation. Most gratefully, it acknowledges the valuable participation of farmers and their very useful contributions in this event.

Likewise, the Commission is indebted to the Government of Himachal Pradesh, particularly its nodal point – the Department of Horticulture, for organizing the Experts Consultation on North West Hill Agriculture on the 2nd and 3rd May, 2005 at Shimla. The Commission is also grateful to the Governments of Jammu and Kashmir, Uttarakhand,
and in particular the host Himachal Pradesh, for deputing their experts and farmers of the States. The Commission also thanks the banks and financial institutions, ICAR Institutions, State Agricultural Universities, NGOs, SHGs, Cooperatives, industries, etc. in the region for their active participation. The valuable participation and contributions of farmers are most thankfully acknowledged.
CHAPTER - 4.2

ENHANCING PRODUCTIVITY, PROFITABILITY, STABILITY AND SUSTAINABILITY

ARID AGRO-ECOSYSTEM

4.2.1.0. Introduction

4.2.1.1 Arid and semi-arid regions occupy nearly 40% of geographical area of India (Figure 1). These areas primarily depend on low and erratic rainfall, but intensity of aridity and severity of problems like water scarcity, drought, fragility of natural resources, hardship, poverty and livelihood security are more in the one-third arid areas than in the two-third semiarid region. In arid ecosystem, the main issues relate to survival and livelihood security of nearly 9 million families and of about 45 million livestock whereas in semi-arid ecosystem the main issues relate to sustainability and productivity (Table 1).

Figure 1. Arid and semi-arid regions of India

\( cv = \text{Coefficient of variation} \)

4.2.1.2. The arid region receives <450 mm annual rainfall with 40% to 60% coefficient of variation against 450-850 mm rainfall in the semi-arid region. Evapotranspiration is four to five-fold higher than that of rainfall in the arid region, while it is only two times higher in semi-arid region. Therefore, severity of aridity, deficit water balance, scarcity of water and problems of drinking water are much more acute in the arid region. Natural resources like water, land, and vegetation in arid areas are very fragile, weak, and partly non-resilient, hence prone to irreversible degradation and desertification under excessive pressure of human and livestock population.

4.2.1.3. **Arable cropping is not a dependable proposition in arid region.** Only one crop can be taken in good rainfall year in arid region, while semi-arid regions reap one assured kharif crop and have good potential of double cropping. On an average, one year of good harvest is possible in arid region during a cycle of 5 years, while two are expected to have moderate crops and at least two failures are common. Arid region offers limited scope of water harvesting and its recycling, particularly on watershed basis, but in semi-arid region this has adequate potential. **Droughts are more frequent in arid region, leading to death of livestock in large numbers and near-famine situations.** Therefore, droughts in arid region often necessitate large-scale contingency relief measures and disaster management.
4.2.1.4. Considering the above issues, Govt. of India launched the Desert Development Programme (DDP) for arid region while majority of the semi-arid regions were covered under Drought Prone Area Programme (DPAP). Hence emphasis in arid regions has to be more on resource conservation, controlling of wind and water erosion, and sustainability of agriculture at optimum productivity level. Typical watersheds are uncommon to arid region. Therefore, the unit of execution of sustainable land management should be an index catchment, a cluster of villages or a dhani or even a watershed, if available.

4.2.1.5 Notwithstanding the harsh agro-ecological settings, arid zones are endowed with several distinct assets and opportunities. There is abundance of land, especially waste and degraded lands, which could be converted into productive systems. There is abundance also of solar and wind energy which may provide opportunities for harnessing renewable power for agricultural purposes, especially agroprocessing and small-scale irrigation. The cold arids are particularly suitable for production of off-season vegetables, flowers, fruits and seeds. The rich and unique biodiversity of crops, tree species, cattle and buffaloes and a large number of medicinal and aromatic plants gives unique opportunities for economic and employment diversification. Some of the rare animal breeds, such as Tharparkar, Gir, Sahiwal and Rathi cows, Surti, Zafarabadi and Murrah buffaloes and the famous Pashmina goats hold unparalleled opportunities for livestock-led development of Indian Agriculture. The rich traditional knowledge and wisdom of the local people of the arid zones constitute additional treasure. Therefore, the future development of arid zone is closely linked with the future prospects of growth of livestock and horticulture sub-sectors in these areas. The Government of India had stipulated a growth rate of 8 percent in both these sub-sectors in order to achieve an overall growth rate of 4 percent for agriculture as a whole. Given the huge gaps in transfer and adoption of proven technologies both in horticulture and livestock sub-sectors, there is ample scope for achieving and maintaining the projected growth rate during the next few years atleast in the horticulture and livestock sub-sectors of arid zones. Therefore, policies geared to the development of arid zone agriculture should give priority attention to horticulture and livestock.
4.2.1.6. The contrasting situations and differences in scale, severity and issues of livelihood in arid and semi-arid regions demand that arid regions be separated out for an exclusive policy for drought proofing, land management and livelihood security, and not clubbed together with the semi-arid regions to make policy decisions for the ‘rainfed areas’ as a whole. This study gives an analysis of the challenges, issues and opportunities exclusively in arid agro ecosystems and focuses on pathways to synergise livelihood security, sustainability and equity.

4.2.2.0 Distribution and Characteristics of Arid Agro Ecosystem

4.2.2.1. The arid agro eco-system is spread over 31.7 million ha under hot arid and 7 million ha under cold arid region, accounting for 12 percent of the geographical area of the country. The hot arid region mainly covers Rajasthan (19.6 m ha), Gujarat (6.2 m ha), Punjab (1.5 m ha), Haryana (1.3 m ha) and small pockets in Andhra Pradesh (2.1 m ha), Karnataka (0.9 m ha) and Maharashtra (0.1m ha) (Figure 2).

![Figure 2. Hot arid areas in India](image)

4.2.2.2. The hot arid zone is characterised by scarce natural resources and inhospitable climate. The annual rainfall varies from 100 mm to 400 mm with erratic distribution (9-21 spells) from July to September. The region experiences extremes of temperature (-2 to 480 C), high solar radiation incidence (450 to 500 cal per sq. cm/day)
and high wind velocity. Strong winds with sand storms are experienced during May-July, when southwest monsoon sets in. The soils are generally light textured (60-90% sand), single grained, dry for most part of the year having acidic moisture regime and hyperthermic thermal regime resulting in poor vegetation cover, high soil erosion and sand dune formation under arid regimes.

4.2.2.3. The cold arid zone (7m ha) is spread in the States of Jammu & Kashmir and Himachal Pradesh. Ladakh - Leh in Jammu & Kashmir and Lahul - Spiti in Himachal Pradesh are the main concentrated belts, characterized by long winters, with huge temperature variation between 40°C to -40°C and with little (about 90 mm annually) or no rains. The population density in the cold arid region is lowest in the country ranging from 2 to 5 persons per sq km.

4.2.2.4. Arid zones are the most disadvantaged areas in India. Coupled with the permanent negative moisture balance and meager availability of surface water, water stress for the crops, other plants and livestock is very high, and the biological productivity is much lower than in the adjoining semi-arid tracts. Associated with this is the low resilience capacity of the natural resources, high vulnerability to degradation processes, including wind and water erosion and salinization (nearly 41 to 85% groundwater being saline). Moreover, high human and livestock pressures on land in the hot arid areas make the region highly unsustainable and less productive.

4.2.2.5 Emphasis in arid zones must, therefore, be on resource conservation, controlling of wind and water erosion, and sustainable land management for attaining optimum productivity level from crop and livestock sectors. The concept of sustainable land management considers land as a matrix of all the parameters like soil, water, vegetation, topography and weather, and aims at maximizing economic yield through efficient use of inputs in relation to the amount and quality of outputs, but at the same time ensuring protection of the environment in the long term and social security of future generations. Diversified agriculture with emphasis on efficient use of the limited water for farming, and integration of economically important perennial trees/shrubs and grasses to stabilize
the production and sustain the livestock production system need to be given greater attention. Animal wealth provides sustainable support to livelihood, but not yet well organized.

4.2.2.6 The various ecological, environmental, institutional and infrastructural handicaps have exacerbated instability and livelihood insecurity problems in arid ecosystems. **Uncertainty and risk factors bear heavily on cultural and social behaviour, resource conservation and utilization and technology adoption.** The unholy nexus among the various handicaps must be broken by the synergistic force of policy, technology, skilled humanware, market, institutional credit and people’s participation. The core issues to be tackled in arid agro ecosystems are land, water and biodiversity security; fodder, feed, livestock and food security; and livelihood security (Figure 3).

**Figure 3. Reiterative forces of poverty and livelihood insecurity in**

4.2 3.0 **Changing Cropping Systems and Land Use Patterns**
4.2.3.1. Increased population pressure and socio-economic demands are forcing changes in farming systems in arid zone. For instance, the human population of western Rajasthan is 22.50 million, which is estimated to reach 27.5 million by 2010 and 33.9 million in 2020 with an increase in density from 108 to 132 to 165 persons per km². Average size of holding has declined from 17.77 ha in 1951 to about 6.00 ha now, and is likely to decline further to 4.00 ha by 2020. About 11% of the rural households own 50% of land in the region whereas 47% hold 10% and the rest are landless labour and nomads subsisting on grazing lands/wastelands. The livestock population being as large as the human population, the pressure on grazing lands is very high.

4.2.3.2. The demographic and socio-economic pressures have brought significant changes in land use pattern. The traditional values and practices like protecting trees and animals, sacred forests and grazing lands, water conservation through Khadins and Tanka, long fallow etc. have undergone rapid decline during the last few decades. Dryland farming integrated with animal husbandry has been the prominent land use in the region, where short and long-term fallowing of land, with emphasis on agro-forestry, was most common. New cropping and farming systems have emerged during the post-independence era.

4.2.3.3. Sensing satellite data suggest that wastelands with pastures of different kinds cover about 30% area, mostly sandy waste but there are also other categories of wastelands. These lands are ideally suitable for rangelands and silvi-pasture in less than 250 mm rainfall, and partly for agro-forestry, including cultivation of pearl millet, arid legumes, clusterbeans, etc. in 250-500mm rainfall zone. There has been an increase in intensity of cultivation across the region, and more and more fallow and marginal land are being brought under plough, so much so that 39% increase has been registered in net sown area during the last five decades, at the cost of 25% decline in fallow land. As more and more marginal lands are being brought under plough, grazing lands are also shrinking.

4.2.3.4. The major shift in arid zone agriculture was brought in by the introduction of the Indira Gandhi Nahar Pariyojana (IGNP) system. This has transformed the
agricultural scenario in the command areas of the canal, and has vastly improved crop production from the area, but at the same time it has resulted in degradation of the land, especially through waterlogging and salinization (> 190,000ha already affected and about 370,000 ha potentially sensitive). **The irrigation system was unfortunately unaccompanied with drainage system.** In the Banni area of Kachchh, which used to be regarded as the best and the largest natural grassland in Asia, invasion of salinity and *Prosopis juliflora* has degraded the grass communities beyond repair.

**4.2.3.5. Declining groundwater has been a major concern in recent times.** Due to over exploitation, use of crops with higher water requirement, intensive cropping and low rainfall, the groundwater is declining at an alarming rate of 20-40 cm per year. Nearly 75% area encompassing 60 blocks of western Rajasthan has become critical grey zone as it has been over-exploited with respect to groundwater and there has been almost negligible groundwater recharge. In addition, nearly 65 % area in Thar Desert has saline groundwater, having at places fluoride and nitrate levels beyond the permissible limits, thus compelling people to use scarce surface water storage for drinking. Ingress of soil salinity in coastal areas poses yet another serious problem.

**4.2.3.6. Cropping systems covering cereals, oilseeds, horticultural crops and cultivated fodders need major attention and focus in arid agriculture.** **About 90% of the cultivable land is being used for cropping.** The net sown area has risen from 38% in the late 1950s to 50% now. Double cropping has also spread in 7-8% area due to expansion in surface and groundwater irrigation facilities. However, **nearly 70 per cent of the sown area continues to remain under rainfed drylands.** About 21% farmers have an average farm size of >10 ha, 32% have 4-10 ha, 22% 2-4 ha, and 25% have less than 2 ha. The major crops in the region are pearl millet, clusterbean, green gram and sesamum, with average productivity of 150 to 250 kg grain and 500 to 1000 kg fodder ha\(^{-1}\). Under irrigated conditions the main rabi crops are cumin, isabgol, wheat and mustard.

**4.2.3.7. In western Rajasthan there has been a steady rise in the area under different crops and their productivity, excepting *kharif* pulses.** For example, pearl millet production has almost doubled between 1961 and 2000, while its productivity increased
by 123%. During this period, there was 35% fall in production of *kharif* pulses. In Rajasthan as a whole, *kharif* cereal production has increased from 17.5 lakh tonnes during the First Five Year Plan to 38.3 lakh tonnes during the Ninth Five Year Plan. There have been larger increases in production of *rabi* cereals, from 14.93 lakh tonnes to 68.8 lakh tonnes. Sharp increases were noticed in the case of oilseeds production. While *kharif* oilseed production in the State increased from 1.17 lakh tonnes during First Five Year Plan to 10.5 lakh tonnes during Ninth Five Year Plan, the *rabi* oilseeds production increased from 0.93 lakh tonnes to 20.86 lakh tonnes during the same period. The phenomenal increase in oilseeds production is attributed to the expansion of irrigation facilities, other technological breakthroughs, high market demands and high profit margins. Unfortunately, oilseed production demands irrigation, and the chief source of water over large area of its production is groundwater, which is falling rapidly in many areas of the arid region.

4.2.3.8. **Table 2** gives area and yield of main arid zone crops in Rajasthan (accounting for about 62% of the country’s arid area) *vis-à-vis* rest of India. It may be seen from the Table that *guar*, pearl millet and certain oilseeds are special crops of arid zones. Directed research and development attention to these crops should be a high priority to exploit the inherent abilities of these highly nutritious crops to contribute to nutritional adequacy, livelihood and sustainability of the inherently fragile ecosystems of arid zones.

4.2.3.9. Increases in coarse cereal production like pearl millet, in spite of its low market value, are largely due to its continued use for subsistence in the rural Rajasthan, as well as use of the non-grain parts as fodder for domestic animals. Development of short duration high yielding hybrids (65 days crop) has been instrumental in increasing pearl millet production in arid zones. Higher vulnerability to weather changes and volatile nature of pulse market did not show such trend inspite of government support. It has been observed that the **average productivity of major crops grown in the region can be further increased by 2 to 3 times with the adoption of improved production technological components** like efficient rainwater management, suitable timely tillage and sowing operations, selection of improved varieties, appropriate intercropping and
crop rotation systems, efficient soil fertility management, proper plant protection measures, including weed management, and contingency/alternate crop planning under aberrant weather situations. However, it is also realized that these technologies work during normal to mild drought years only.

* Figures in parentheses indicate the percentages.

4.2.3.10. During abnormal years of moderate to severe droughts (like in 1988 and 2002), the risk of negative return from dryland crop cultivation is so high that the farmers are reluctant to adopt any improved dryland farming technology as a package. Although traditional land use systems like mixed cropping, agro-forestry with *Prosopis cineraria* and *Ziziphus nummularia* are still practiced, these need to be refined and placed in proper perspective for agricultural sustainability.

4.2.3.11. To cushion the adverse effect of drought, mixed sowing of seeds of various dryland crops, may be 2 or 3, is undertaken depending on micro-farming situation and need. Sowing of pearl millet, clusterbean, moth bean and sesame in an approximate ratio of 8:2:2:1, and thinning of pearl millet population during drought as per the needs and use it as green fodder are normal practices in the region. However, this practice hampers efficient crop management from sowing to harvest and threshing. Pearl millet being a staple food crop, farmers take it on more than 60% of the sown area, but the crop is more vulnerable to drought and late onset of monsoon (beyond 15th July).
4.2.3.12. Research results show that a reduction in the area under pearl millet to 40% and putting the rest 60% of the holding under kharif legumes (30%), oilseeds (15%) and forage crops (15%) could be profitable. For such crop diversification intercropping systems like mung bean/clusterbean + pearl millet (2:1), sesamum + mung bean/moth bean/cowpea (2:1), castor + moth bean (1:3) are helpful.

4.2.4.0 Horticulture-led Diversification

4.2.4.1. Arid zone horticulture and horticulture-based land use as means of diversification of traditional agriculture are being increasingly considered in developmental plans and policies both in arid and semi arid regions. The climatic conditions are conducive for production of quality fruits and vegetables. The sharp fluctuations in day and night temperatures during autumn, spring and summer help in development of sweetness in kinnow, sweet orange, ber and date palm and flesh colour and sweetness in pomegranate arils and mateera pulp. The intense solar radiation and high wind velocity can be utilized in various farming related activities. The fruits like aonla, custard apple, pomegranate and citrus (kinnow, sweet orange) are coming up well in arid climate. Medicinal plants like isabgol and seed spice cumin are already export items from Rajasthan and Gujarat. In this context, changing global policy environment due to WTO, the advantages of dry climate particularly in relation to quality and lesser incidence of diseases and pests should not be overlooked.

4.2.4.2. The cold arid region is suitable for quality production of temperate and rare fruits such as seabuckthorn, exotic vegetables and vegetable seeds. Apricot is a commercial crop in Ladakh and sold as dried apricot. Kargil area is well known for dried apricot. Top working of seedling trees of apricot with improved cultivars amenable for drying has been standardized. This will help in upgrading the quality of the produce from the existing orchards. Technologies for drying of apricot, tent drying and osmotic dehydration techniques have also been developed. But these have not been widely accepted, even though it is reported that osmotic dehydration results in increase of retail price of apricot by seven times (Rs. 140 per Kg against Rs.20 per Kg for traditionally dried pulp).
4.2.4.3. In vegetable crops, technology developed and popularized by DRDO laboratory in the high hills for vegetable growing under low cost polyhouses has become highly popular for higher yields, extending growing period and for production of good quality seeds of cole crops. The ‘trench technology’ developed under National Agricultural Technology Project (NATP) has also revolutionized off-season cultivation of vegetables (even in winter) due to higher conducive temperature in dug out trenches. Strawberry cultivation in trenches in Kargil area is gaining importance.

4.2.4.4. Among spice crops, identification of high yielding genotypes of Kala Zeera (SKUKZ- Shong; SKUA –BZ –8-6-1) and standardization of agro-techniques including propagation have helped its commercialization. Similarly, R&D efforts in standardising both production and post harvest technology in saffron have already started paying dividends by enhancing production and quality of saffron in J&K. Patent applications have also been filed for value added saffron pigment and flavour/concentrates based on research efforts.

4.2.4.5. The vast land resource, valuable genetic diversity, surplus family labour, increasing canal command area and developing infrastructure are the other prospects for development of arid zone horticulture. Besides, Central Government Organizations, State Departments of Horticulture and Agriculture, KVKs, NGOs etc; four ICAR institutes and eight SAUs along with setup of AICRP and AZF are providing a reasonable infrastructure for research on various aspects of arid horticulture. More than hundred scientific manpower is directly involved in the promotion of arid horticulture in the country.

4.2.4.6. At present only about 95 thousand ha and 110 thousand ha area in the arid zone is under fruits and vegetables, respectively, giving production of only 0.92 and 1.32 million tonnes. The projected requirements of 2.4 and 5.0 million tonnes by 2020 AD, therefore needs that the production of fruits be increased three times and that of vegetables four times of the current levels of production (Table 3). Moreover, export requirements of horticultural produce and products are expected to grow very fast in the
post–GATT scenario. The peculiar dry and warm blend in the arid region agroclimate offers opportunity for producing quality products of high health standards. This obviously would require R&D preparedness.

4.2.4.7. **Agroforestry plays vital social and economic roles in the fragile ecosystem of arid zones.** Apart from *Prosopis cineraria* (Khijri) and *Technomella indulata* (Marwar teak) based agroforestry models, *Ailanthus* has a very good economics of soft wood and green fodder during scarcity months. Shelter belt plantation along Indira Gandhi Canal has provided good dividends. *Prosopis juliflora* is flourishing in saline soils of Kutchchh in Gujarat – a problem from the point of view of grass pastures, but could be an opportunity to increase fuelwood production from the degraded land.

**Source:** Central Institute of Arid Horticulture, Bikaner

4.2.4.8. Wastelands can be profitably used for growing medicinal and oil-bearing plants, which have high national and international demands. Many of the species growing wild (e.g., senna), or being threatened (e.g., guggal), and other species having very high survival rates in certain environments (e.g., *Aloe vera*), can be grown on the large wastelands of the region, which will not only stabilize the landscape, but will also provide good income to the farmers.

4.2.4.9. **Rajasthan is the leading State in production of seed spices** like coriander, cumin, fenugreek and chilli. There is wide scope to further increase the area
and production. The crops like fennel and ajwain also show good promise. The production of seed spices during 2000-2001 in coriander, cumin, fennel and fenugreek was 2.31, 0.39, 0.28 and 0.93 lakh tonnes, respectively. In case of chilli, Andhra Pradesh is the leading state with almost 49.1 percent of country’s total production, while the share of Rajasthan is about 6.2 percent. More than 90 percent of the spices produced are used in domestic market but there is a good demand in the export market both as raw and value added products.

4.2.4.10. Some of the Medicinal and Aromatic Plants (MAP) like Isabgol, Ashwagandha, Opium poppy, Senna, Guggal, Safed Musli, Henna (*Lawsonia inermis*) grow well in hot arid /semi-arid areas with high recovery of actual ingredients of medicinal value. Henna is known for the natural dye and its commercial export potential is about Rs. 80-100 crores. Already the spread of henna in Rajasthan and Gujarat is reported to cover 35000 ha. Similarly, senna, a medicinal plant is reported to cover about 11000 ha in Rajasthan and Gujarat, where both marketing associations have been formed and processing units established.

4.2.4.11. Isabgol, the seed coat which is known in trade as Psyllium husk or husk is medically important. The crop is cultivated in parts of Gujarat, Rajasthan and Madhya Pradesh as a *rabi* crop. The crop requires cool and dry climate and India is the sole exporter of Isabgol husk in the international market. Another important medicinal plant ‘Safed Musli’, the faciculated roots of which are used in preparation of many vital tonics, has become popular for cultivation and has immense commercial prospect. ‘Guggal’, categorized as an endangered species in the Red Data book, is naturally distributed in the drier parts of Gujarat and Rajasthan and offers good scope for commercial exploitation for its medicinal value. Standardization of propagation techniques of Guggal through stem cutting has enhanced its scope for large scale cultivation.

4.2.4.12. In the cold arid zone, *kala zeera* (*Bunium persicum*) is an important spice crop, growing wild. Due to R&D efforts, its cultivation had spread over 373 ha in Srinagar, Kinnaur, Lahul - spiti and Chamba districts. The benefit: cost ratio of this crop
is reported to be 2.39:1. The crop is likely to spread in larger areas. Saffron, the golden condiment, is the legendary crop of Kashmir and identification of high yielding clones and better post harvest technology have enhanced the scope of better income generation from this crop.

4.2.4.13. A good number of MAPs grow in wild habitat of cold desert region (Kinnaur and Spiti) of Himachal Pradesh. Surveys show illegal exploitation and marketing of medicinal plants from cold desert region. Some of the MAPs, namely, Sarlampanja (Dactylorhiza hatageria) and Atish (Aconitum heterophyllum) are reported to be highly priced items.

4.2.4.14. A National Seminar on Commercialization of Horticulture in non-traditional areas held on 5-6 Feb 2005, at the Central Institute for Arid Horticulture, Bikaner, has identified the following thrust areas for expansion of Arid Horticulture:

- **Mass multiplication of recommended varieties of fruits and vegetables** by National Seed Corporation, State Seed Cooperation and other line departments like Department of Horticulture, Agriculture and State Farm Corporation etc.
- **Promotion of nursery activities** by progressive farmers and nurserymen if efforts in item No. 1 need supplementation to meet the total requirement.
- **Large-scale demonstrations of crop diversification technologies** on farmers’ fields and promotion of animal based components for integration in crop diversification.
- **Promotion of pressurized irrigation and water harvesting structures for orchard establishment.**
- Promotion of **integrated nutrient management** including organic cultivation of arid horticultural crops.
- Emphasis on **IPM** and ensuring timely availability of quality agri inputs including agri-chemicals.
- Establishment of **pilot plants for commercialization of value added products.**
- Organizing **capacity building** programmes at different levels.
4.2.4.15. The recently announced National Horticulture Mission should have a specific window for Arid Horticulture to ensure integration of production, post harvest management, processing, value addition and marketing.

4.2.5.0 Livestock: The Anchor of Livelihood Security in the Arid Zone

4.2.5.1. Livestock provide income support to two-third of the population in arid Rajasthan and are the mainstay of desert people. Most importantly, **ownership of livestock in arid agro-ecosystem is positively egalitarian.** For instance, average number of buffaloes per ha holding for marginal and small farmers is about 2 animals whereas for medium and large farmers it is 0.44 and 0.13 animals, respectively (Table 4). Livestock rearing, integrated with crop farming, has proved to be the most viable option in the region, as it stabilizes farmer’s income during the poor rainfall years and **saves farmers from acute distresses, even from suicides** (so frequently reported from semi arid regions of Andhra Pradesh, Karnataka and Maharashtra).

Table 4. Category-wise ownership pattern of livestock in Rajasthan

4.2.5.2. Rearing of cattle, sheep, goats and camels on cultivated land, common grazing land (including oran), etc., is prevalent. Recent animal census has revealed alarming decline in population of camel and sheep, while goat, which is more drought-hardy and is comfortable with the prevailing low amounts of browsing resources, did not decline much. Buffalo, which is exotic to the region, has shown doubling in population during the past 15 – 20 years (Figure 4). With the increase in productivity of individual animals, while the overall production of livestock has steadily been increasing, the
livestock density has decreased in the recent years, dropping from 160 livestock per sq km in 1997 to 143 in 2003 – a healthy change indeed.

4.2.5.3. Drought-hardy breeds of cattle, sheep and goats are required to be integrated in farming systems of the region, looking into the aspects of breeding, feeding and management of livestock. Farming systems involving animals + grasses + crops + trees + shrubs + horticulture, may bring about perceptible change in the life of people. Off-farm employment and per capita income of the rural people can be considerably increased through appropriate farming system.

4.2.5.4. The arid region constitutes 30 percent of total sheep, which produces around 40 per cent of total wool production of the country (Table 5). The sustainability of the sheep production is facing challenges as the pasture and common grazing lands are reducing everyday and there is increase in pressure on these lands. The sheep serves the need of food in the form of meat and milk, of clothing in winter in the form of wool and skin and of maintaining and enriching the soil fertility in the form of manure. Sheep farming is further facing decline with the reduction of pasture land due to advent of canal irrigation system in western Rajasthan. The sheep production system is required to be viable, sustainable and economically competitive with an objective to increase production per unit of land. **Intense effort is required to develop research**
based, regionally relevant, ecofriendly and economically viable sheep rearing practices, meat and wool technologies that could be adopted in different arid settings of the country with varying scale of inputs and investments.

4.2.5.5. The Central Sheep and Wool Research Institute, Avikanagar, in collaboration with the Department of Animal Husbandry, Govt. of Rajasthan, aims to transfer technologies for improving sheep production through breeding, nutrition, animal health, pasture development, wool utilization and techniracy. The emphasis is on Institute Village Link Programme to achieve an overall integrated development in adopted villages. Socio-economic studies are underway towards improving not only sheep production but also alleviating poverty of sheep farmers. Socio-economic survey of sheep and goat breeders are conducted to achieve this goal. The average annual real income of sheep breeders has been increasing by 8 percent per annum.

4.2.5.6. Arid agro ecosystem, with nearly 23 million goats, accounts for about 16 per cent of the country’s goat population, against 12 per cent of the total geographic area, highlighting relatively higher concentration of goats in arid agro ecosystems. In arid zone, a marginal farmer on per ha basis keeps nearly four goats as against two buffaloes and cattle. Goats in the cold arid contribute about 40 metric tonnes of Pashmina, the costliest animal fiber for garments. Goat meat has the advantage of being preferred by all the communities and the demand invariably exceeds the supply. The goat milk contributes more than 4 percent of total milk produced in India, yet its greatly dietary value and superior milk products have not been recognised and exploited for export. The
skins of Indian goats are considered to be of very high quality. The poor man’s cow, especially in arid zones and in isolated cold hilly regions, goats offer new opportunities due to:

- Preference of **lean meat** of goat by consumers in India and abroad.
- **Tailor-made foods from goat milk** to better fit the human needs.
- **Goat milk products are being recognized as important health foods** especially cheese, paneer and yogurt and these are parts of cottage industry.
- **Goat butter - a valued consumer item as it contains short and medium chain fatty acids.**
- Valued as the **best bio-organic manure producer.**

### 4.2.6.0 Challenges, Issues and Opportunities in Arid Agro-Ecosystem

4.2.6.1. The arid agro-ecosystem suffers from low and erratic rainfall, degraded soils and poor crop and livestock productivity. Coupled with poor socio economic base and infrastructure the small and marginal farmers living in these vast tracts are unable to improve their livelihood due to stagnant income and lack of alternate options of income generation. Acute shortage of fodder also limits the livestock productivity. Adoption rate of new technologies is low due to poor investment capacity, risk aversion and inadequate extension services. Rainwater is the critical input in determining the productivity in all these areas, but the inability of managing erratic and deficit rainwater through proper harvesting methods has always been a constraint in upgrading productivity. Soils are highly deficient in major and a few minor nutrients. The erosion of top soil by wind is a widespread problem. **The major challenges and constrains are:**

- **Low and erratic rainfall, high evapo-transpiration, extreme aridity**
- **Scarcity of water, frequent droughts and famines**
- **Sandy, saline and gypsiferous degraded soils with micronutrients deficiencies and low fertility; heavy wind erosion of top soil**
- **Water logging and salinization in command areas**
- **Deep, brackish (high fluoride and nitrate content) and declining ground water, ingressing sea water**
• Low and fluctuating crop and livestock yields and acute fodder shortage, degraded grazing lands
• Poor marketing, processing and value addition
• Poverty, illiteracy, conservative society, poor socio-economic base and infrastructure
• Risk aversion and poor adoption of new technologies.

Recurrent droughts are the main constraint with multiple adverse effects. For instance in Rajasthan, in the 2002 drought, separately nearly 45 million people and 45 million livestock were affected, loosing nearly US$ 1 billion worth agricultural products and over 6 million mandays of employment (Table 6). The worst victims of drought are livestock, as their numbers dip by a couple of millions in each severe drought (see Figure 4) year due to forced slaughter and death resulting from poor nutrition and starvation.

</tbody>
</table>

4.2.6.2. Against the above weaknesses, the arid agro ecosystem offers windows of opportunities to capitalize and increase income and livelihood of the rural people. The important endowments and opportunities are:

• Abundance of land and mineral resources
• **Abundance of solar and wind energy**
• **Rich biodiversity**, multipurpose tree species (MPTs), nutritious grasses and high quality snow water; rich genetic resources of fruits, vegetables, seed spices and medicinal and aromatic plants.
- Adapted human and **drought hardy animals**; Tharparker, Gir, Kankrej, Sahiwal, Rathi, Nagauri breeds of cattle (their purity although threatened); Mehsana, Surti, Jofrabadi, Murrah, Nagpuri and Khunni buffaloes, besides Pashmina goats of cold desert and other animal breeds are unique genetic treasures of Indian arid zones

- **Traditional wisdom and strong social structure.**

The different regions of the arid agro ecosystem have their specific challenges and opportunities, as described below.

**Hot Arid Zone**

4.2.6.3 The major challenge in this chronically drought-affected region is sustainable land management that ensures not only adequacy of food, fodder and drinking water, and livelihood support. Inclusiveness and guarantees both for on-farm and non-farm employment are important. Since the region is affected by recurrent drought, crop failure is a regular feature and farmers practice agro-forestry of different kinds and integrated livestock-crop farming. Such integration of crops with animals, trees, shrubs and grasses in a farming system mode helps not only in drought-proofing, but also provides multifarious food, animal, fruit, fodder, fuel and timber products.

4.2.6.4. Water is the most demanding resource in the region, especially during drought. Although the region has traditional wisdom on water harvesting, pipe water supply has gradually deteriorated many structures. Using new technologies developed by various ICAR institutes, SAUs and other NARIs, many of the tankas, nadis and khadins could be revived. For a successful and sustainable dryland farming enterprise, conservation of soil and water resources has to be willingly and religiously undertaken by farmers as an integral component of the production system practised by them.

4.2.6.5. Suitable intermixing of livestock with agroforestry systems can enhance the ability of desert dwellers to sustain under the unpredictable and harsh environment. Livestock farming, though a traditional practice, still lacks a proper scientific and holistic approach. The major bottlenecks in its progress are non-availability of fodder and
drinking water, and shifts in land uses towards extensive and intensive crop farming that have resulted in shrinking grazing resources. Also, infrastructures for mobility of the perishables, processing units for livestock products (e.g., dairy industry), and their marketing facilities, need serious attention.

4.2.6.6. An economic evaluation of the alternate landuse systems shows a benefit-cost ratio of 1.46-1.87 over 1.24 under the arable cropping. This proves the worth of crop-grass-tree-animal system over exclusive arable farming under arid ecosystem (Figure 5). Despite there being compelling scientific and economic reasoning in favour of agri-pasture, agro-forestry and silvi-pasture that can also enhance livestock production system, the average farmers in the region still have apathy towards agri-pasture or silvi-pasture. As mentioned earlier, the region is most suited for livestock-based farming system, yet developments in livestock production systems and their linkage with market economy have not progressed much.

![Figure 5. Benefit: Cost Ratio of different alternate landuse systems](image)

4.2.6.7. Another major issue is over-use of the scarce groundwater resource for growing high water-demanding crops. At the current rates of groundwater exploitation, large areas of double cropping will turn into either wastelands having saline-sodic soil, or will revert back to mono-cropping.
4.2.6.8. The third major issue is long-term management of drought, rather than ad-hoc contingency planning for relief, ensuring livelihood support and continued employment, possibly in non-farm sectors. Frameworks for a symbiotic relationship between farm and non-farm sectors need to be established. These complex socio-economic issues need environmentally sound, yet workable policy frameworks. Perhaps, the stakeholders, State, NGOs and GOs may have to work as a consortium for the desired results.

**Cold Arid Zone**

4.2.6.9. Cold arid zone is characterised by long frozen winter months and very low snow fall and rains and short growing period adversely affect agricultural growth of land-based economy in Ladakh and adjoining areas in stagnant. The soil and water resources have been shrinking and pastures have been declining. However, unique biodiversity, extreme temperature regime (−40 to + 40°c), low RH (40%), maximum sunny days (300 day / year) and pest and disease free environment are some of the rare features of cold desert eco-system which can be converted to opportunities, if planned properly.

4.2.6.10. In cold arid areas, **off-season production** (July–September) of vegetables and flowers for other areas can be successfully ventured. Use of **polyhouse** for vegetable cultivation has become quite common, giving the growers benefit of extended growing season, besides freedom form pests and diseases. Among fruits, apricot is a commercial crop in Ladakh area and sold as dried apricot, which is quite popular outside the region. Kargil area is famous for quality produce of black cumin (*kala zeera*) and seabuckthorn is being explored commercially. This zone is a **rich repository of medicinal herbs**, most of which are used in Tibetan system of medicine. The Lahul - Spiti belt is famous for production of disease free seeds of vegetable crops, including seed tuber of potato.

**Southern Arid Agro Ecological Setting**

4.2.6.11. The Southern Arid Zone is situated in the rain shadow region of SW monsoon along the leeward side of Sahyadris. The mean annual rainfall varies from 500
mm in Bellary to 573 mm in Bijapur (both in Karnataka) and 550 mm in Anantpur (Andhra Pradesh). A large number of seasonal crops (sorghum, pearl millet, castor, pigeon pea, groundnut, chickpea etc.) and perennial (ber, custard apple, pomegranate, aonla, mango in fruits and *Casuarina, Dalbergia sissoo, Acacia nilotica*, neem etc as tree species are grown in the region. Better rainwater management, tree crop-livestock interface, arid-horticulture, biodiversity plantations and livestock-based farming systems offer opportunities in the semi-arid region. Dry land orchards of mango, cashew, tamarind, jackfruit are receiving promotional support. With drip irrigation, grapes, pomegranate, acid lime and sweet orange are important commercial successes in this region.

4.2.6.12. The APEDA has developed a concept of Agri-Export Zones (AEZs) and AEZs focusing horticulture produce / products have already been set up in Andhra Pradesh and Karnataka. AEZs have been established for rose, onions and gherkins in Karnataka. Contract farming has been found to be successful in gherkins and it is reported that VST Natural Products Limited in Andhra Pradesh was able to have contracts with gherkin farmers by providing seeds, credit and other technical inputs for supplying raw gherkins which were processed and exported. Such models may work well for other export oriented crops. Semi-arid zones with provision of supplementary irrigation (micro-irrigation) can produce exportable commodities matching international quality standards by following hazard analysis and critical control point (HACCP) guidelines and Codex standards.

4.2.7.0 Pathways to Sustained Livelihood Security of Arid Zone People

4.2.7.1 In line with the priorities identified under the National Common Minimum Programme of the UPA Government, the Department of Agriculture and Cooperation of the Ministry of Agriculture has formulated a new scheme on “Enhancing Sustainability of Dryland Rainfed Farming Systems” and submitted it to the Planning Commission for approval. The proposed scheme aims at addressing issues like rainwater harvesting and its utilization; in situ soil moisture conservation; use of organics/organic manures; alternate land use; and adoption of improved dryland farming technologies in the arid and
semi-arid regions of the country. On a 100 percent funding from the Government of
India, during the Xth and XIth Plans, sums of Rs 2150 crore and Rs 7,000 crore,
respectively, are proposed for implementation of the scheme. At the national level, the
implementation of the scheme will be monitored by the National Monitoring Committee
chaired by Secretary DoA.

4.2.7.2 The above initiative is indeed a welcomed move. But, it has the risk of running
into the same shortcomings as all rainfed programmes in the past which had generally
failed to adequately address the farmers’ problems of survival and livelihood security
specific to the hot and cold arid regions and had drifted towards the relatively more
congenial settings of semi arid areas. Therefore, it is advisable not to club the arid
zone research and development programmes with those of the semi arid zone. This
report, thus, addresses the challenges and prospects exclusively of arid agro-ecosystems.

4.2.7.3 All efforts should be synergised and channeled to ensure survival and
livelihood security of farmers and rural people (as also of livestock) in arid zones
braving acute water scarcity, frequent droughts and near-famines. Congruence of
ecological, economic and employment securities should be ensured through the
participatory development and adoption of eco-technologies towards a rational
blend of productivity, sustainability, profitability and equity. Significant
adjustments, as discussed below, are required in the areas of policy actions and critical
interventions such as technologies, institutions, human resources, investments market and
infrastructure to achieve the goal.

A. Policy Actions

National Authority for Dryland Farming Areas: Convergence and Synergy

4.2.7.4 The greatest distress to farm and rural communities occurs in the drylands of the
arid and semi-arid regions of the country. Nearly 76% of the farmers committing suicide
were dependent on rainfed dryland agriculture. These areas primarily depend on low and
erratic rainfall, but intensity of aridity and severity of problems are more in the one-third
arid areas than in the two-third semi-arid region. The situation regarding groundwater
use and drawal, which accounts for nearly 70% of the total water used for crop production, is alarming. The principal constraints observed in reaping the full benefits from dryland farming research and development are the following:

- Lack of disaggregated and focused approach, gross operational overlaps among concerned Ministries and Departments with little monitoring and evaluation of emptye number of related programmes.
- Lack of integrated watersheds and sustainable land development approaches, with all members of the watershed and SLM community not working together to save and share water and land.
- Lack of social synergy in the area of land and water use planning, with little emphasis on collaborative efforts in both the production and post harvest phases of farming.
- Dry lands soils are both thirsty and hungry. It is important that steps are taken to overcome these two constraints by judicious water harvesting and use, and by applying to the soil the needed micro and macro-nutrients. The water crisis, especially the fast receding groundwater and quality, and hunger of the soil caused by micronutrient deficiencies need to be addressed on a priority basis.

4.2.7.5 With the above backdrop, as already stipulated in our First Report, we strongly recommend the establishment of a National Authority for Dryland Farming Areas (NADFA) (Figure 6). The Authority will be hosted by the Ministry of Agriculture, with synergistic horizontal linkages with all concerned Ministries and Departments. It should be a multistake-holder entity performing normative as well as policy development and implementation functions geared towards sustainable livelihood security of dryland area people. Its main functions may be:

(i) Formulation, updating and implementation of dryland agriculture research and development policy and programmes.

(ii) Priority setting, direction-giving, coordination, removal of gross duplications, monitoring and streamlining of fund allocations and utilization.
(iii) Supporting and sponsoring sustained institutional and social capital and human resources development and establishing and managing linkages.

(iv) Promoting enhanced water conservation, productivity, equity and sustainability.

(v) Improving post harvest technology, value addition to crop and animal products and developing end-to-end approach to link production with market, leading to enhanced and sustained income and food security.

Figure 6: National Authority for Dryland Farming Areas (NADFA)
4.2.7.6 In order to address the differentiated problems and prospects of the semi-arid and arid regions, the Authority may set up separate National Committees for Integrated Watershed Development for Semi-arid Regions and for Sustainable Land Development for Arid Regions (Figure 6). These should be constituted and function as a multistakeholder consortia for monitoring the outcomes of the various programmes and collaborations and for making mid-course corrections, if necessary. The various Watershed Development Projects, Mission Mode Projects, such as National Horticultural Mission, Dairy Mission, Oilseeds Mission, Drinking Water Mission, and Drought Relief Programme must function in an integrated manner and internalize the location specificities to synergistically address local problems and to achieve the set objectives (Figure 7). The arid and semi-arid zone States should constitute State level counterpart Committees, which co-jointly with the National Committee, should ensure timely flow of the earmarked funds to Panchayats at the ground level through the District IWD and SLM Consortia (see Figure 6). The Consortia will be the main technical backstopping units comprising experts from relevant technical fields, development agencies, farmers, private sector, financial institutions, NGOs and other concerned stakeholders. These should be headed by full time experts in the field.

Figure 7. Convergence and synergy among various Programmes and Missions
Sustainable Land Management for Livelihood Security

4.2.7.7 Recognising that acute water deficit, frequent droughts and fragility of land and other natural resources are the distinguishing features of the arid zones, and appreciating that typical watersheds are uncommon to arid agro ecosystems, **Sustainable Land Management (SLM)** should be the focus in arid zones around which should rally all interventions towards sustainable livelihood security. The approach should visualise land as a matrix of soil, water, vegetation and weather. There should be convergence and synergies around SLM to ensure optimal sustainable production and conservation of the ecosystem (**Figure 8**).

![Figure 8. Sustainable land management: multiple benefits](image)

4.2.7.8 The policy must emphasise that land, water and vegetation in arid regions are finite and have limited capabilities. Sustainable **demographic policy and awareness** should be developed by the Government of India and carefully implemented by State Governments to rationally contain population and population-driven over-exploitation in such fragile agro ecosystems which lead to irreversible land degradation, desertification.
and migration of people. Unmindful adoption of “quick-fix” technologies, such as growing rice at the cost of rapid groundwater depletion or rearing buffaloes despite scarcity of fodder and drinking water needs a critical appraisal. Environmental costing through adopting available or locally-developed environmental-economic indicators should be compulsorily implement by State Governments to deter the misuse of the scarce resources.

Harnessing Group Dynamics

4.2.7.9 NABARD, other banks, SFAC, concerned ministries and departments should facilitate public-private linkages not only in infrastructural development but also in promotion of rural entrepreneurship and in establishment and effective functioning of SHGs, cooperatives, Small Farmers’ Estates, other rural groups and community based organisations, agriclinics and agribusiness centres to facilitate access to quality inputs and to fair markets. The Government of India and State Governments should suitably strengthen Panchayat Raj Institutions, congrueing authority, financial capacity and accountability to mobilise grassroot level priority setting, programming and implementation in close collaboration with suitable NGOs and CSOs, particularly in establishing public-private sector partnerships to facilitate technology transfer, establishment of rural SMEs and producer-oriented remunerative marketing. The Smallholder Farm Estates will not only provide the power of economies of scale but will also forge synergy and convergence among various actors and stakeholders and among various processes of production, processing and marketing. Using an end-to-end approach, the Estates should establish strong backward linkages with technology, inputs, services and credit and other institutional supports and forward linkages with remunerative markets, income generation and profit sharing.

Agriculture-Risk Fund: Institutional Life Saving Support

4.2.7.10 Institutional credit flow to arid zone farmer is extremely low. These farmers try to minimize their income risks by taking up different economic activities. The banks need to provide credit for a composite set of activities which may include cultivation
of crops, some horticulture, small animal husbandry and may be a micro non-farm enterprise, unlike other areas where financing for one economic activity is the general practice. The need is, therefore, to look at these farmers differently and provide them credit line in a more flexible manner keeping in view their investment requirements and income flows. Another important aspect is the recurrent and frequent droughts which cripple their income flow rendering the borrowers from banks defaulters and credit unworthy. Rescheduling and restructuring of these loans is not enough in the event of successive droughts. The indebtedness would keep increasing and further accentuate the distress. Under these circumstances, the Central Government may step in to create an Agriculture-Risk Fund to provide relief to the farmers in case of successive droughts. This Fund should have contributions from the Central Government, State Governments and the banks in a predetermined fashion.

Insurance: Insulating the Farmer from Risks

4.2.7.11 Given the high risk, coupled with the poor economic condition of the farmers, many of whom are already acutely stressed, an effective insurance mechanism covering the majority poor is a sine qua non for sustained livelihood security of arid zone farmers. The provisions and coverages under the existing Agricultural Insurance Corporation of India (AICI) are inadequate as these generally cover the bank borrowers who represent only a small fraction of the comparatively better-off people particularly in arid zone, where the outreach of the banks is poor. Special insurance products, covering crops, livestock and health of the farming families as a composite micro insurance scheme need to be designed for these areas. Special dispensation to the AICI for developing and marketing such insurance products is required. Intensive efforts are needed in many blocks of the arid zone, which have been generally bypassed, by earlier programmes and initiatives. It may be appropriate for the Central Government to provide premium support, say to the extent of 50%, for this insurance coverage as an essential life-saving support system.
Contingency Funds for Sustaining Agriculture and Livestock in Drought Years in Arid Zones

4.2.7.12 The arid zones are frequented by droughts every other year. **Contingency plans** for meeting the farmers' requirements of seeds and other inputs are prepared by the State Government as well as the Central Government including the ICAR. However, most of the State Governments, because of the financial constraints, are unable to provide the required assistance to the farmers. The Ministry of Agriculture, Government of India, also does not have any fund or schemes which may be utilized by State Governments for the purpose. It is, therefore, felt that a *revolving fund of Rs 500 crore may be created in the Ministry of Agriculture, Government of India, for meeting such expenses*. It is suggested that these funds can be provided by suitable reappropriation by the Ministry out of the unspent approved budget estimate under the various Central Sector and Centrally-Sponsored Schemes.

Enhance Investment in the Distressed Areas

4.2.7.13 The all-time low investment in agriculture notwithstanding, the investment in arid zones is paradoxically still lower. The inhospitable weather conditions and frequent droughts have deterred even the public sector from investing in arid zones. Whatever little, the private sector investment is confined to the environmentally better endowed and congenial areas, such as irrigated areas. This has widened the divide between arid agro-ecosystems and other agro-ecological regimes. The following actions are essential towards providing basic facilities and entitlements and for bridging the divides:

- Both, Central and State Governments, should **substantially increase investment in arid zone areas** for agriculture as well as for infrastructure, education and primary health care development, which will also encourage the private sector to investment in these hitherto 'non hospitable' areas. Provide **tax holidays** and other incentives to private sector to encourage multilateral investments.
Investment in irrigation, especially micro-irrigation and overall soil and water management, should have high socio-economic and ecological pay off.

- **Strengthen research, technology development and extension system** in a strongly affirmative and need based mode, with emphasis on resource conservation and sustainable use and on marketing and socio-economic aspects. At least 15 per cent of the development budget should be earmarked for on-farm strategic research to facilitate refinement and quick adoption of technologies.

- **Augment human resource and skill development** to enhance gainful employability particularly of the rural youth.

- **Engender all agricultural development programmes**, particularly livestock, horticulture, seed and herbal production, processing and marketing programmes.

- Create and strengthen each village as a knowledge centre and establish agribusiness and agriclinic centres, and **promote entrepreneurial systems**.

**Synchronize Trade Policies with Development Policies**

4.2.7.14 Trade, particularly in the liberalized and globalised world, is to be seen as a major development tool. If not handled properly, it will prove detrimental to the welfare of the farmers, especially the smallholders. For instance, development of livestock (which are so very important in arid zone) is closely linked with the trade policies of the Government on dairy products and wool. **The GOI should not liberalize import tariffs on these commodities which will jeopardize domestic production of the vital livelihood resources.** Moreover, for the speciality and monopoly commodities, namely isabgol, guggal, cumin, pashmina and others, special trade and pricing policies and strong enabling mechanisms, such as an effective and responsive SPS system, should be created to meet TBT and non-tariff barriers as well as to maintain our market share.

**B. Catalytic Interventions**

**Income, Food and Nutritional Security**
4.2.7.15. Arid areas have been carrying relatively greater loads of poverty, under nutrition and unsustainability. This unholy alliance among the three maladies could be broken only by a still stronger alliance of increased and sustained productivity, profitability and social justice (Figure 9). Equally strong alliance should be forged (and monitored) by the Task Forces on Arid Agro-Ecosystem at National, Provincial, District (the District SLM Consortium) and Village (Gram Sabhas and PRIs) levels for adoption of proven technologies and development strategies for enhanced productivity, creation of increased marketable surpluses by small farmers, prevention of post-harvest losses, value addition and remunerative marketing. The following actions are recommended for enhancing income, food and nutritional security:

- **Enhance productivity and quality** through the adoption of appropriate ecotechnologies to attain desired competitiveness. Adopt end–to-end approach of development of selected commodities, such as ber, date palm, seed spices in hot arid zone and apricot and *kala Zeera* in cold arid zone. Promote diversification particularly towards horticulture and other high value commodities and intensify production by adopting low-cost green houses, microirrigation and fertigation. A special date palm project involving 40 demonstrations and 40,000 ha under commercial production, including low cost green houses for hardening vitroplants should be completed in the next five years.

- Promote integrated farming system, coupled with marketing, with special focus on livestock-based farming system, especially sheep, goat and camel economy in the hot arid regions and Pashmina goats and new Bharat Marino and hybrid angora rabbits in cold arid regions. Fifty pilot projects in hot arid and 25 in cold arid zones should be launched.

- Strengthen value addition through better post-harvest processing and management and promotion and large scale adoption of new horticultural, herbal and livestock products and efficient marketing system. Due care should be taken of local sensitivities in locating the meat and other such industries.
• Undertake **niche production of hybrid and other vegetable seeds** especially by women SHGs and local cooperatives and establish grain, feed, seed and other fodder banks to be managed by SHGs.

• **Adopt a whole life cycle approach** to the integrated implementation of all nutritional programmes, starting with pregnant women and ending with old and infirm persons.

• **A special programme should be launched for development of the cold desert region** of Ladakh to enhance the productivity, quality, profitability and sustainability of its farm enterprises. Eco- and other tourism should be further assisted through new initiatives such as Rare Birds Park. Human resource development should be accorded high priority for capturing new off-farm job opportunities.

![Diagram](image)

**Figure 9. Breaking the unholy nexus**

4.2.7.16. **The National Rural Employment Guarantee Scheme (NREGS) should be extended to enhance economic as well as physical access to food and also to create assets in integrated watershed and sustainable land development programmes.** The Scheme should be linked with the Food for Work Programme (FFWP) to ensure sustained food security to be regularised under a proposed **National Food Guarantee Act** (See Chapter
2). Techniracy should be promoted by Programme Implementation Agencies and District SLM Consortium to develop **skilled human resources** who could be employed more gainfully.

**Employment Security**

4.2.7.17. Arable cropping is not a dependable proposition in arid zones, especially for small holders. Therefore, alternative and complementary sources of income and livelihood must be developed. For this, **off-farm and non-farm employment** opportunities must be created by the Government as well as by the private sector. Government policies, such as tax incentive to the private sector, development of rural infrastructure, reorientation of research and technology development priorities to generate and transfer technologies for rural people, particularly resource poor farmers, and diversification of the use of the local resources as well as of agro ecological endowments are prerequisites for creation of off- and non- farm employments. It may be added that, almost two decades ago, China took almost 100 million people out from the agriculture sector and employed them in manufacturing and services sectors related with agriculture and primary production systems. For this, China had developed the necessary rural infrastructures, rural agro industries and market connections. Most importantly, the country had made arrangements to train those people and increased their skills in specific areas for their out-of-agriculture redeployment. Similar approach should be adopted by the Central and State Governments in India.

4.2.7.18. Unique features of arid zones should be harnessed for promoting off-farm and non-farm employments. These include ecotourism, spiritual tourism and sports tourism and promotion of agro processing especially based on horticultural and livestock products. For instance, the high dietary value and superior milk products from goat milk could constitute important export products. Further, leather industry based on the huge livestock population of arid zones could be a highly paying proposition, both from the angles of employment as well as income generation. Agroprocessing and value addition industries for horticulture and medicinal and aromatic plants should be promoted in rural areas and small rural godowns should be established to facilitate marketing. Other sources of non-farm employment are the promotion of handicrafts and cottage industries.
Economic activities based on local resources such as marbles, minerals and other deposits should also be promoted to diversify employment opportunities. However, these activities should be consistent with the requirements of environmental sustainability. While the private sector must play a leading role in increasing and diversifying employment opportunities, preference should be given to the local people to avoid migration and social conflicts. However, in order not to compromise with efficiency and competitiveness necessary training and skill development programmes should be established by the State Governments to train the local people seeking the alternative employment.

4.2.7.19. The following micro enterprises and marketing approaches are strongly recommended to be adopted towards the goal of enhanced employment, productivity and livelihood security, especially by landless and non-agricultural people:

- Intensification and spread of household income generating activities like mushroom cultivation, sericulture, backyard poultry, apiculture and vermicomposting.
- Promotion of custom hiring of farm machinery, tools and plant protection equipment etc.
- Establishing and fostering linkages with market committees by e-networking
- Linking SHGs and other farmers organizations/groups with credit, insurance, private & corporate sector to promote Small Holder Estates to benefit from the power of economy of scale.
- Establishing ICT based knowledge centre/internet kiosks for market information and virtual extension service.

Conserving and Utilizing Every Drop of Water

4.2.7.20 Rainwater harvesting: Reviving the “Dying Wisdom”: Water for agriculture or even for drinking is the key issue of arid region and must become the concern of everyone to conserve every drop of water. In Western Rajasthan, the hub of the country’s arid zone, adopting an integrated water management programme, the
“dying wisdom” of traditional system of rainwater harvesting in *tanka, nedis, khadin, talab*, etc., should be revived and restored. New technologies developed by ICAR and other institutes for the purpose should be widely demonstrated and adopted. In this context, nearly 1,000 field demonstrations are proposed to be organized by State Governments. Community surface water storage facilities should be provided to all the needy villages where the piped water supply of the Public Health and Engineering Department (PHED) is inadequate to meet the drinking water needs. With an additional rainwater surface storage of 137 mcm, raising the total capacity to 531 mcm, domestic needs of all arid villages of Rajasthan not covered by PHED could be met. About 70-80% harvesting of rainwater may provide community storage to all. Over time, the capacity of *Khadins* and other water storage structures have decreased due to land degradation and crop intensification. Improvement of these devices and structures through enhancing and sensitizing group awareness and their better management are the needs of the hour (Table 7). Panchayats, Gram Sabhas, community organizations, NGOs and CSOs must play major roles in this effort.

**Table 7. Requirement of traditional rainwater harvesting structures**

4.2.7.21 **Groundwater recharge:** Groundwater recharge must be made compulsory for urban as well as rural settings. Due to negative water balance and higher withdrawals, there is hardly any build-up of groundwater in arid regions. Though starved for water, arid regions also face floods, may be once in 10 years, as recently witnessed in the arid agro ecosystem of Gujarat, which may generate on an average 2100-6200 mcm water. **It is estimated that if 1/3rd of floodwater is made to recharge the groundwater,**
it can sustain five recurring droughts. Ephemeral river water should be used to recharge groundwater through check dams, percolation tanks, sub-surface barriers, sand fill dams, induced recharge, etc..

4.2.7.22 Water resource development and management: **Irrigation water being the most critical input in crop production in the arid eco-system**, restoring water bodies and promoting water harvesting should receive major developmental support. Under Desert Development Programme (DDP), National Watershed Development Programme for Rainfed Areas (NWDPRA), Integrated Watershed Development Programmes (IWDP), Drought Prone Areas Programme (DPAP) and the like, water resource development activities have been promoted by GOI, but often in isolation. These efforts must be converged and synergised at the action site. For instance, several of these programmes have tried agricultural land contour graded bunds and contour vegetative hedge (CVH) as “run-off retention” devices to conserve moisture in situ and for improving infiltration. But, in light soils of arid region, such measures may not be very effective. Efficacies of such efforts must be improved by fine tuning of the technologies through a collaborative, integrated and participatory approach. Emphasis on location specificity and precision is the key to the success in all arid zones. The Task Force on Arid Agro Ecosystem should critically examine the outcomes of these programmes with focus on arid zones where little work has been done as compared to that in semi arid and other zones, and prepare a detailed time- and location-targeted action plan to converge and complement the ongoing activities. About 10 percent of the total investment in watersheds and soil conservation should be allocated for development and fine tuning of technologies for Sustainable Land Management in arid agro-ecosystems.

4.2.7.23 The feasibility of rainwater harvesting through farm ponds in areas with rainfall above 400 mm has been well established. Also, there are many examples of recycling such harvested water for successful raising of horticultural crops. It is estimated that in arid region there is potential of harvesting 70% of rain water for recycling as well as ground water recharge. Under NATP, seven check dams were constructed in
different areas, which led to recharging of ground water, by 80 m in Matyana watershed area of Junagarh in Gujarat. It is claimed that in four years time farmers could reap economic benefits as a result of sale of fruits and crops raised through use of the water for supplementary irrigation. Such “bright spots” should be used for training farmers and extension staff and should be replicated widely by State Governments. Diggi-cum-sprinkler irrigation programme should also work well for vegetables. Similarly, Diggi-cum-drip system developed in CIAH, Bikaner (Rajasthan) may work well for fruit species.

4.2.7.24. In Andhra Pradesh, over 42 lakh ha have been covered by watershed and 9300 micro-watersheds have already been delineated. Similarly, in Karnataka, over 6 lakh ha are under watershed development. Community water management through participatory planning, water audit and district water management agencies are in the water management agenda in A.P. Promotion of micro-irrigation is one of the thrust areas in Karnataka and the State Government has earmarked Rs. 6 crores for drip irrigation for 2005-06.

4.2.7.25. Through Watershed Development Society or Watershed Committee, with farmers participation as per IWDP guidelines, the water resource development for multi-purpose use in arid zones need to be augmented and managed by using participatory approaches. The Panchayats, especially the Pani Panchayats, self-help groups, the SFEs and other grassroot organizations should undertake group operations for water harvesting and management. The Task Force should identify the “nuts and bolts” of the various proven technologies and approaches for water conservation and its efficient use and ensure their time targeted replication in designated areas, as mentioned above.

4.2.7.26. Develop quality micro-irrigation: Pressurised or micro irrigation - drip and sprinkler, should be extensively promoted both by Central and State-Governments for increasing water use efficiency and productivity. So far, generally only larger and well-to-do farmers have benefited from the Central and State Governments’ supports (subsidy) to micro irrigation. Moreover, as usual, the subsidy programmes were not handled
properly and substandard and defective equipment hardwares flooded by spurious firms have choked the water flow and the scheme. The process must be freed from corruption and a transparent people-managed programme with clearly defined responsibility and accountability of stakeholders, supported with a quality control and a close monitoring mechanism, should be established. Coupled with fertigation, micro-irrigation could revolutionise protected agriculture/horticulture through the widespread use of low-cost greenhouse technology. The good beginning made in Kachchh and a few other arid areas should be multiplied by the extension and concerned development agencies of the State Government in other analogous arid agro ecosystems, converting the grey deserts into green and blooming deserts. NABARD, other development banks and private sector (primarily through contract farming) should find the initiative attractive enough and jointly undertake replication and diffusion of the technology.

4.2.7.27. **Traveling workshop:** In order to learn from the successful experiences of other countries on water management in arid agro-ecosystems, a traveling seminar comprising experts from Israel, Egypt, Turkey, Jordan and USA (Arizona) should be organized by the MoA. The Indian team, after a detailed briefing, should start the field visit and on-the-spot discussions starting from the entry point of the Rajasthan Canal in the arid zone and to all other agro-ecologically different regions of the agro-ecosystem. The “hot spots” where recent tensions on water sharing in the Indian arid zone (resulting in a few farmers’ death in Rajasthan) should also be visited to assess the ground problems and solutions. Farmers, NGOs, development agencies, ICAR, SAU and State Govt. representatives should join the seminar. Its findings should critically be analysed by the Task Force of the NADFA and presented at the national level in the presence of all stakeholders and concerned ministries and departments and internalized in the national water policy. If necessary, an Indian team comprising the various stakeholders should visit successful sites and experiences abroad.

**Drought Proofing, Risk Avoidance and Management**

4.2.7.28. The damages caused by droughts, year after year, are huge and destabilizing. Consequently, the Government has to provide equally huge relief funds, with little asset formation and durable impact. In fact, **the drought budgeting during**
the past five years has been higher than the budgeting for irrigation. In order to obviate this recurring loss, several steps, as enumerated in the following paragraphs, should be followed:

4.2.7.29. As mentioned earlier, Special Integrated Agriculture Insurance Programmes, coupled with institutional credit and life-saving assistance programmes should be implemented for arid zone people. Although NABARD and other specialized commercial banks have developed credit plans at district levels and circulated a number of bankable schemes, there is not much credit flow for development of arid agriculture. Bankers generally treat the farmers as borrowers and not as clients. State developmental plans need to be formulated in consultation with the bankers, who must become more farmer-friendly and development-oriented.

4.2.7.30. Complementarily, schemes are needed for adequate drought proofing through popularization of integrated farming and mixed cropping systems by cultivation of agricultural and horticultural crops that are high value and are known for extreme drought tolerance with minimum funding support. Long-term measures such as wind breaks and shelter belt plantation and reinvigoration of local techniques and traditional wisdom for water conservation (reviving the ‘dying wisdom’ and the nadi, tankas and khadins) should be promoted by State Governments, including SAUs, the Consortium, Panchayats and grassroot organizations. Water literacy and peoples participation in management of water should assume high priority.

4.2.7.31. In order to reach the needy and to enhance effectiveness of such schemes, the criteria for classification and delineation of areas as arid, semi-arid and drought prone need to be revisited by the NADFA. Group dynamism and power of partnership should particularly be harnessed in arid agro ecosystems for mutual reinforcement of confidence of the various stakeholders. Development by small-marginal farmers through SHGs may eventually establish effective Small Farmers’ Estates (SFE) which will bring desired convergence among various processes of production, processing and marketing and establish and operate grain, fodder, feed, seed
and water banks each numbering about 700. These moves will help create off and non-farm employment opportunities.

Judicious Land Use Planning and Use

4.2.7.32. Selection of crops and cropping systems: The State Land Use Boards, State Extension Department, SAUs and farmers together should select crops and cropping systems in arable lands considering rainfall, soil type, length of growing season, marketability and household needs. Replacing low yielding cultivars with improved high yielding ones, which are resistant to abiotic and biotic stresses and optimizing their agro-techniques can easily reduce 20-30 percent cropping area without sacrificing grain production. Low rainfall areas (150-200 mm) and light textured soils with 8 weeks’ growing period should be kept for *Lasiurus sindicus* grass, range management and moth bean varieties like RMO-40, CAZRI-Moth 1, 2 and 3. Areas receiving 200-400 mm rainfall and 8-10 weeks’ growing period are suitable for short duration legumes, cluster bean, sesamum and agro-forestry. The areas having more than 400 mm rainfall, heavy soil and 8-12 weeks’ growing period should be kept under pearl millet, guar, cowpea, and sesamum. Dual-purpose pearl millet variety, providing good grain and fodder yield, such as CZP-9802, should be preferred.

4.2.7.33. Rotation and inter-cropping with legumes: There is sufficient data at CAZRI showing that pearl millet after clusterbean produces double the grain yield compared to that obtained under mono cropping. Inter-cropping with legumes boosts the yield of the companion crop. Therefore legumes should be introduced in sequence or in rotation for improving fertility and productivity of arid lands.

4.2.7.34. Revolution with specialized arid zone cash crops: Arid region is endowed with drought-hardy species of medicinal and aromatic plants, spices and condiments. There are areas which are highly suitable for growing crops like isabgol, methi, mehndi, cumin and medicinal and aromatic plants. As trees have got long gestation period, and reduced crop yields, farmers are inclined to shift to cultivation of these specialized cash crops. Through post harvest and value addition and proper liaison
with industries, economy of arid region can be revolutionized by commercializing these cash crops. Based on the edapho-climatic conditions, crop zones for pearl millet, mustard and special crops should be delineated. Farmers should accordingly be trained and educated by District SLM Consortium and extension agents for growing these crops, their post-harvest management and for improving their economy.

4.2.7.35. **Soil test based micro-nutrient amendments for increasing yields:** Nearly 80-100 per cent of the tested farmers’ fields in several pockets of the arid zone were severely deficient in boron, zinc and sulphur in addition to the macro-nutrients like nitrogen and phosphorus. Farmer participatory trials with micro-nutrient amendments increased crop yield by about 50 per cent. The economic gains with the application of micro-nutrients were substantial. This technology should be adopted on large scale throughout arid areas of the country. Additional facilities for soil test analysis for all the 16 macro and micronutrients are needed to implement this programme. To begin with, the Central Government may assist each arid zone district to establish one adequately equipped soil testing laboratory which could reliably test for the various nutrients, especially the micronutrients. The SAUs and their KVKs should be actively involved in this task. Additional investment both in terms of equipment and human resources are required to create credible soil testing laboratories.

4.2.7.36. **Animal-based farming system and good grazing practices:** Animals are the mainstay of the arid agro ecosystem. An integrated livestock based farming system, with focus on pastures, horticulture, medicinal plants, bio-fuel and oil bearing plants should be endeavoured. In the process, culturable wastelands, marginal lands and non-arable lands can be fruitfully utilized for pasture development and silvi-horti-pastures for animal husbandry. Sandy wastelands can also be fruitfully utilized for shrubs and grasses. But, poor grazing practices and high stocking rates, particularly in the sub-alpine pastures have denuded the pastures, sometimes beyond rejuvenation as exotic invasive weeds have replaced the native vegetation. The NDDB cooperative model for production-marketing link for milk and milk products should be adopted throughout the zone.
4.2.7.37. **Fodder production:** In order to overcome the main bottleneck of the paucity of fodder, the scarcity being 35 per cent during normal rainfall years and as high as 75-80% in drought years, to meet the demand of the huge livestock population in the zone, incentive should be given to farmers to grow fodder crops in part of their lands. Livestock–based farming system should attempt reduction in pearl millet area from 60 to 40 per cent while increasing legumes form 20 to 30 per cent, oilseeds from 10 to15 and forage from 10 to 15 per cent. It has been worked out that in a seven-hectare farming system model, agro-horti may be assigned 30 per cent, agro-forestry 25 per cent, agri-pasture 15 per cent and silvi-pasture 10 per cent. Nearly 300 demonstrations of this model are proposed in the arid zones of Rajasthan, Gujarat and Haryana.

4.2.7.38. **Fodder bank:** The fodder is generally imported from neighboring states during drought at exorbitant rates. During good rainfall years there is a high potential of production of fodder from wastelands, marginal lands, community lands and by assigning some parts of arable lands. **High priority should be given to the production of fodder and creation of fodder banks for the locally grown fodder.** About 1,200 fodder banks are proposed. These fodder banks need to be created at Panchayat Samiti level, preferably with the involvement of SHGs and SFEs, and the fodder can be utilized during scarcity period/drought. Further, with the availability of fodder block machines, both stationary and mobile, **compressed fodder bricks and bundles, easy to transport and store, should be produced at large scale and stored in the fodder banks.** Such bricks, also made of straw plus urea plus molasses could be made in the adjoining States of Punjab, Haryana and Westerns UP (where surplus straw is available and is often burnt in the field itself) and transported into Rajasthan or other needy states for immediate consumption or for augmenting the fodder banks.

4.2.7.39. **Management of cattle:** During a drought year, a large number of cattle are let loose or sent to gaushalas, which is a unique way of management of cattle population. There are more then 226 gaushalas in arid region of Rajasthan, Jodhpur district alone hosts about 146 of them. These gaushalas have been created for philanthropic reasons, and act as cushion for cattle management during stress. The by-
product of gawshalas are utilized as medicines, insecticides, manures etc. These noble institutions should be encouraged and promoted by State Governments through providing veterinary assistance and training of the caretakers for adequate upkeep of the animals.

4.2.7.40. **Saline water fish culture:** Production of **Scampi** in saline water accumulated due to over irrigation and inappropriate water management in major canal command areas, such as Indira Gandhi Naher Pariyojna (IGNP) in Rajasthan, is a profitable proposition. The technology is indigenously available and special extension efforts and incentives should be launched by the States using the saline soils/water for production of Scampi. A benefit: cost ratio of about 1.5 has been realized under several trials in these settings.

**Mechanization of Arid Zone Agriculture**

4.2.7.41. **Precision and timeliness of agricultural operations are fundamental to the success of arid zone agriculture.** Further, for maximum output we have to shift to high-tech agriculture in selected areas that require greenhouses and specialized equipment for precision farming. There is also need for developing energy-efficient implements for various operations. Trials at various levels have revealed that **crop productivity, operation cost and time and inputs efficiency can be increased by 25 to 50 per cent through mechanization, thus increasing farmers’ income by about Rs.3000 to Rs. 5000 per ha.**

4.2.7.42. Feed and fodder shortages are major concerns in arid regions, especially during drought years, when large-scale transportation of fodder becomes too voluminous and, hence, cumbersome. Therefore, appropriate mechanization of harvesting, bailing and storage of fodder is a necessity. Further, harvesting of perennials like Henna, Kair, etc. need special tools.

4.2.7.43 With the increased emphasis on horticulture-led diversification in arid zone, and considering that horticultural harvests are generally perishable, rural processing and value addition will be essential to ensure suitable prices and prevention of post-
harvest losses. Suitable low-cost processing machines will need to be popularized in rural areas.

4.2.7.44 Quality production of equipment through local industry, improving availability of costly implements to farmers through custom hiring centres and capacity building of farmers, industry workers and entrepreneurs are key elements of arid zone mechanization policy framework. Supports of Central as well as State Governments are needed in the following aspects of mechanization:

- **Creating strong R&D centres** for arid zone mechanization.
- **Developing training infrastructure** for capacity building of farmers, operators, industry workers and entrepreneurs of custom hiring centres.
- **Linking banking institutions** for financing different activities including purchases by farmers for setting industry and custom hiring centres etc at reasonable rate of interest.
- **Simplified, smooth and transparent flow of subsidy** to resource-poor farmers for procuring implements and small machines.

**Preserving Livestock Heritage and Establishing Gene Banks**

4.2.7.45 The National Bureau of Plant Genetic Resources, The National Bureau of Animal Genetic Resources, The National Bureau of Agricultural Micro-organisms and other concerned Central and State agencies, in collaboration with local communities, should help chronicle and digitise inventories of the bio resources of the hot and cold arid zones covering plants, animals, fish and microorganisms. **Genetic and gene literacy movement should be launched for all stakeholders, especially the farmers.** An **integrated conservation strategy, in situ, ex situ**, including suitably managed field repositories, will be needed for converting the biological wealth into economic wealth. There is scope for introducing and commercialising exotic germplasm such as of cactus, pear, quandong, cardo, African dove plum, organ tree, marula nut, nance, oyster nut and other nuts. But, this must be done only in accordance with the SPS and IPR provisions, and the three Bureaus must play the Leading role in this context.
Traditionally, many of the finest Indian cattle milch breeds like, Tharparker, Gir, Kankrej, Sahiwal, Rathi etc have been evolved from arid regions of Rajasthan and Gujarat. Buffaloes, particularly the breeds like Mehsana, Surti, Jafrabadi are popular in arid regions of Gujarat, Murrah in Southern Haryana and Nagpuri in parts of Maharashtra. **But due to unscientific and uncontrolled cross breeding, the quality of some of the excellent livestock is on continuous decline.** For example, one of the hardiest and best breeds of Tharparker cow has only 10 per cent now. The excellent ‘Nagauri’ breed, which is famous for draft bullocks, is being relegated due to the use of tractors. In Gujarat, Khunni buffalo, which is capable to subsist on zero management, is on the decline due to degradation of Banni grassland in Kachchh district. These trends should not only be arrested but must be reversed. In fact, our **rich national animal heritage and genetic resources are seriously threatened.**

In order to safeguard the precious germplasm, it is recommended that a part of the **Suratgarh Farm (in Rajasthan) of the Government of India should be developed as an ex-situ germplasm repository of arid zone livestock.** The centre should also undertake genetic improvement programmes of the local breeds. Quality semen banks to facilitate artificial insemination programmes should also be established at the farm. Additional model animal farms could be developed at strategic locations considering the geophysical characteristics of the area where local breeds could be preserved, germplasm banks could be established and training facilities could be developed on veterinary first aid, AI and improved management practices. In fact, these farms should work not only as a technology transfer centers but should also be instrumental in triggering associated socio-economic changes. **Protection, utilization and further enrichment of wealth of traditional wisdom of the desert dwellers as to how people survived without depletion or over exploitation of natural resources, as well as of tribals who inhabit arid zones in large numbers, is as important, if not more, as the indigenous biodiversity.** Many of the survival and resource conservation and utilization strategies and knowledge are presently under severe strain. Some are no more practiced because of increased demand, weakening of societal control and lack of collective concern. The time-tested values and
traditional knowledge and devices should be systematically documented and fine-tuned to meet local needs and to improve their efficiencies. Several of them provide lead for new and modern technologies. Willing participation and mobilization of local communities and rural institutions from planning through execution in R&D efforts, therefore, assume a high priority. **The PVPFR Act, enacted in 2001, should be implemented to benefit farmers, including tribals, as conservers and breeders.** The National Authority on Plant Variety Protection should be rendered functional as soon as possible. **Loss of a genetic resource is a loss for ever, and it is happening unabated.**

**Socio- Economically and Agro Ecologically Differentiated Approach and Utilization of Special Features of Arid Agro-Ecosystem**

4.2.7.49. In arid areas, natural resources endowment and development potential vary greatly from location to location. The northwest arid zones and southern arid zones are very different in their agro-ecological endowments and opportunities. In this context, non-arable lands from class V should be assigned to class VIII for permanent vegetation like pasture, silvi-pasture or afforestation. Therefore, **location specificity must be emphasized in micro planning, in allocation of resources and in setting socio-economic targets.** Area-based development duly internatilized in the integrated sustainable land use management approach, should be the hallmark of development and growth of arid areas. Therefore, we propose that the ICAR, Land Use Boards and concerned Central and State level agencies should delineate agro ecological sub-regions of the arid districts and the various programmes should be designed primarily by the Consortium to match their capacities. This will particularly be important for creating assets to ensure sustainability of the land, water and vegetational resources. Some of the important action programmes with high socio-economic and agro-ecological pay offs are described below.

4.2.7.50. **Seed production:** Recognizing that arid zone offers an ideal environment for producing quality seeds because the infection due to various pests and diseases is very low under these conditions, arid ecosystems should be utilized for producing seeds of
selected crops and can become a “Seed Bank” for the country. Farmers can also earn better income from seed production.

4.2.7.51. **Organic farming:** The level of fertilizer use due to risk aversion is rather low in arid zones. Since productivity or yields in arid zone are stabilized at lower level, these should best be achieved through organic manures. Organics will also improve soil physio-chemical properties and water retention in profile. Agricultural products such as vegetables, fruits, grains, pulses etc. produced organically should be suitably certified and marketed remuneratively for giving higher returns to the farmers.

4.2.7.52. **Harnessing solar and wind energy for agriculture:** Since there is ample of solar and wind energy available in arid zones and coastal belt of Gujarat arid regions, the natural renewable energy should be harnessed traditionally for agriculture and other commercial uses. Many post harvest industries should be integrated with solar and wind power. The R&D institutions, involving SAUs and other non-agricultural technology institutions should work together to design and popularize low cost devices to harness solar and wind energies at village as well as household levels. The State Task Force on Arid Agro-Ecosystem should oversee this activity.

4.2.7.53. **Arid horticulture:** Arid fruits such as ber, aonla, gunda, date, bael have excellent potential for integration in arid zone farming system. It was observed that even in extreme drought of 2002, ber crops fetched $1/3^{rd}$ of income through horticulture while there was complete failure of crops in the arid areas. Therefore, arid horticulture should be strongly promoted by State Departments of Agriculture and/or Horticulture for drought proofing and to improve the economy of arid land farmers.

**Special Attention to the Cold Arid Zone**

4.2.7.54. With more and more employment avenues open to the local people today in non-agricultural sector, the land-based economy stands neglected in cold arid zone. However, this situation could prove to be extremely short-lived as the current boom that
Ladakh, Lahul - Spiti and other tourist places are experiencing cannot be considered sustainable. Moreover, much of the opportunity is being mopped up by non.locals. Thus, **there is an urgent need to make land-based occupations more remunerative and economically rewarding.** At the same time, local capacity must be built (particularly in the sphere of entrepreneurship) to help locals tap the commercial possibilities of this sector. The Ladakh Autonomous Hill Development Council (LAHDC) and State authorities in Himachal Pradesh and Uttaranchal should ensure that the conservation of natural resources supporting the land based economy and the move towards increased cooperation between the various stakeholders that are a part of it could be adopted as additional measures.

4.2.7.55. The natural resources that support the land-based economy are themselves deteriorating rapidly. Soil is getting eroded due to the incessant mining of this precious resource. Similarly, water resources (especially glaciers) have been receding for the past many years, purportedly due to the effect of global warming. Pastures have been severely neglected resulting in poor forage availability. This in turn is largely because of the lack of proper irrigation facilities, which has put a severe constraint on the development of the livestock industry in the region.

4.2.7.56. New strategies should be adopted by the LAHDC, particularly the Horticulture and Agriculture Departments to meet the above challenges. Firstly, the region must reduce its dependence on the outside world for critical requirements such as food by strengthening agricultural production and productivity. Traditional technologies should be judiciously blended with modern technologies to build on the time-tested approaches. Diversified integrated farming systems encompassing use of organics and service exchange systems should be pursued. The indigenous and traditional knowledge systems should be protected and gene banks for conservation of the rich biodiversity should be established. Further, additional land should be brought under cultivation and should particularly be allotted to landless farmers for greater equity. Participatory irrigation approaches, adoption of intensive cultivation techniques, greenhouse cultivation, IPM, pasture and forage development, management of zoonotic diseases and optimization of herd sizes and herd insurance should be strengthened. **It would be**
helpful if Pashmina production in Changthang could be raised to 65,000 kg per year and in the rest of Ladakh to 6,000 kg by the year 2025 to maintain the leadership of the region in this highly specialized commodity.

4.2.7.57. Secondly, the interest of the people in land-based economy must be revived. The local people, particularly the youth, must be sensitized and made aware of the important role that agriculture, livestock and horticulture have played and will continue to play in the socio-economic and overall livelihood security of the people in these areas. Training programmes for skill improvement and promotion of land-based entrepreneurship should be undertaken through producers’ groups and Self Help Groups (SHGs) as well as by individuals to streamline the production, value addition and marketing activities. Assistance in the form of credit, marketing infrastructure and support prices will be essential for linking the producers with the consumers.

4.2.7.58. Thirdly, agriculture (in a comprehensive sense) must become remunerative to the farmers and to all those linked with it. The cold arids constitute special niches for vegetable seed production, floriculture (off season cut flowers and bulbs), medicinal and aromatic plants and several highly nutritious rare fruits like seabuckthorn and nuts like walnuts and “exotic” vegetables. In order to receive remunerative returns from these specialty products, strong marketing initiatives, linking the producer with the consumer at mutually beneficial terms should be created. Existing systems such as the HPMC (Horticultural Produce Marketing Corporation), marketing cooperatives, Mandis, and agriclinics should be strengthened through additional infrastructural and database and information sharing facilities. Greater use of small effective machines to enhance productivity of the labour force, integrated soil and water management through the plant, soil and water testing facilities and knowledge-based technological interventions will be essential for increasing overall productivity and profitability. The ICAR should open a regional station of the Central Arid Zone Research Institute (CAZRI) in Ladakh to cater to the technological needs of the cold arid region. Linkages with other initiatives, especially those of DRDO and ISRO
should be ensured. An integrated cold arid area development programme for soil, water and biodiversity conservation should be intensified.

4.2.7.59. Fourthly, the economic growth must be synergized with environmental and ecological security. Priority should be given to pastures improvement, increased efficiency of existing irrigation facilities, and to the creation of additional irrigation resources by harnessing micro irrigation devices and by tapping hydro, solar and thermal powers in a participatory mode. Improved fodder production and sustainable grazing systems and good grazing practices should be evolved and enforced. In this context, traditional migration patterns should be revived and conditions should be created for extended stay at summer pastures, both for herders and livestocks. The socio-economic and cultural interests and roles of the herders and nomads, who are distinct and important component of the cold arids (as also in hot arids) should be duly promoted by the State Governments. Moreover, as climate change is already impacting the glacier regimes and snow lines in the cold arid zones, research and technology development processes should focus on evolving and adopting coping and new climate change management mechanisms, such as creation and maintenance of new artificial water bodies. The proposed National Centre on Glacierology (see Chapter 4.1) should address these issues.

Bridging Technology Gap: Connecting the Disconnect

4.2.7.60. There is almost a total disconnect between research and extension. A good number of Central Research Institutions of ICAR and of SAUs, particularly research through All India Co-ordinated Research Projects (AICRPs), NARP, NATP and others, have developed technologies for arid regions. Pioneering work in natural resource management (NRM) at CAZRI, Jodhpur for arid zone and CRIDA and ICRISAT at Hyderabad for semi-arid zone, on dry land horticulture under AICRP (Horticulture) and at CIAH, Bikaner and on livestock at CS & WRI, Avikanagar, CIRG for Goats at Makhdoom, NRC for Camel at Bikaner and DRDO’s agricultural technology development initiatives at Ladakh alongwith the J&K State Government initiatives are worth mentioning. Production system research (PSR) has generated technologies on land
and water resources, cropping systems, soil microbes, salinisation in IGNP areas, low-cost greenhouse and offseason cropping and production of high value low volume products, including seeds in cold arid areas and characterization and improvement of breeds, brackish water fish culture, feed enrichment and reproductive efficiency improvement in livestock sector. But, only those technologies (as elucidated in Box 1) which had linkage with value addition and marketing have been adopted and majority of the other technologies continue to await adoption.

Box 1.

### Arid Zone Horticulture: Some Success Stories

#### Ber Cultivation
- With the introduction of improved cultivars the area under ber in Rajasthan has increased during 1984 to 1996 from 229 ha to 829 ha. And production from 1387 t to 4145 t.
- Varieties such as Gola, Seb, Mundia, Umran were found to be promising in this region.
- A preliminary survey has shown that 5 million plants are produced every year which generates employment to the tune of 37,500 man days.
- On average Rs. 20,000 per ha is realized as net profit in normal rainfall years. Even in extreme drought condition in 2002 in Rajasthan, ber fetched 1/3rd of the income when there was complete failure in other crops.

#### Henna Cultivation
- Henna (*Lawsania inermis*) is known for natural dye and leaves are used for cosmetic purpose. Its export potential is Rs. 80-100 crores.
- Identification of high yielding MH-1 and MH-2 varieties (3-3.5 q/ha) with high quality of dye and distribution of saplings of improved varieties helped in the spread of henna to about 35000 ha in Rajasthan and Gujarat with a net return of Rs. 10,000 per ha.

#### Senna Cultivation
- Senna (*Cassia angustifolia*), an ideal crop for degraded land with leaves of medicinal value, is a drought hardy shrub.
- High yielding cultivars Tuticorin and Bikana with 8-10 q /ha /year yield helped in spread of senna cultivation to over 11,000 ha in Rajasthan and Gujarat.
- A Senna composite with 3.8% sennoside content, against 2.84% in commonly grown one, has been developed.
- A net return of Rs. 10,000 per year per ha is expected from senna cultivation in arid zone. The estimated export potential of the crop is Rs. 11 crores.
- Marketing associations have been formed for senna and processing units established in Bikaner and Jodhpur.

4.2.7.61. Transferable technologies for sustainable land use and enhancement of productivity of crop and livestock sector are now reasonably well developed. The Angora rabbit production is popular in hilly areas of H.P., U.P., Eastern region and Tamil Nadu.
One Angora rabbit can give net income of Rs. 150 to 200 per year. Such successful experiences should be widely adopted through creating grassroot institutions and public-private linkages. Other transferable technologies include: the Bharat Merino Sheep, enhanced reproductive ability of sheep, hybrid rabbits, fat lamb production, handloom woven blankets, wool camel hair blended products, hand made felts from blended rabbit and sheep wool of inferior quality. **About 2000 large-scale demonstrations of catalytic technological interventions are proposed to be carried out by State Governments in collaboration with private sector, NGOs, SAUs and ICAR to disseminate the technologies.**

4.2.7.62. **Given the pivotal role of livestock and horticulture sub-sectors in arid zones and high perishability of their products, very high priority should be given to post harvest processing, value addition, storage and establishment of cool chains. A post harvest technology wing should be added to each KVK to bridge the gap between production, distribution and pricing. Accordingly, the KVKs should be redesignated as Krishi and Udyog Vigyan Kendra (KUVKs).**

4.2.7.63. **Majority of the technologies developed by the various institutes await transfer and effective adoption. The Poor socio-economic base of small and marginal farmers and inadequate extension services are responsible for slow rate of adoption of new technologies, resulting in huge technology transfer gaps (Table 8). New extension and technology transfer mechanisms are needed to bridge the gaps. Group approach of extension through formation of self-help groups (SHGs) is one such approach. The small farmers SHGs in clusters should be helped to organize establishment of Small Farmers Estates (SFEs) covering an area of 200-500 ha each to capture the economies of scale.** It is proposed to establish 1000 SFEs during the next five years. Landless labourers should be supported with specialized activities like vermi-composting, beekeeping, IPM activities etc. SFEs for horticultural crops will suit well both in arid Rajasthan and Gujarat and semi-arid Andhra Pradesh and Karnataka.
Table 8. Yield gaps (technology transfer gaps), Bijapur

Source: CRIDA, 2004

4.2.7.64. Seed spices and medicinal and aromatic plants (MAP) should be promoted as sources of income to people living under harsh climatic conditions of the deserts. This highly specialized group of crops must be raised with technology backstopping and intensive training of poor farmers in the arid zone. Such skill development training will be effective only through SHGs and SFEs under scattered low population density areas. Wherever advantageous to the farmers, contract farming to ensure remunerative marketing of these specialty crops should also be promoted.

4.2.7.65. Training and follow-on extension support including provision of limited non-repayable micro-capital grant (MCG) to the SHGs and SFEs through making suitable provisions in various developmental schemes need immediate attention. The micro-capital grants will be provided to the groups and estates for adopting modern technologies to improve production, value addition and marketing.

4.2.7.66. Group capacity building will be crucial and structured support / participation of technical personnells both in public and private sector will be required. Services of SAUs, R&D units, KVKs, ATMA's and grassroot organizations should be rendered for organizing training of trainers as well as farmers. Farm schools, representing “bright spots”, numbering nearly 500, will be used for farmer to farmer training. Training focusing women empowerment should concentrate more on gender friendly technologies / messages favoured by women. For example, skills in raising
quality planting materials of horticultural crops and post harvest handling of farm produce may suit women farmers better.

Farmer–Centered Marketing

4.2.7.67. Due to small size of holding and low productivity of arid crops, the quantity of marketed surplus of individual farmers is generally low, which constrains smallholders from bargaining effectively. High transportation cost of small-sized marketable surplus raises the transaction cost. Further, higher inter-village distances make provision of marketing infrastructure like road connectivity, telephone links, location of storage godowns and emergence of processing units, relatively less viable compared to those in densely populated areas. As the public sector investment in infrastructure in arid areas remains a low priority, private investors, of course, show less interest in such investments. Keeping in mind these features unique to arid zone, special support should be provided to the marketing centres, whose success will underpin the livelihood security of the arid zone farmers, as the future productions will increasingly be market-led.

4.2.7.68. Out of 25 agricultural commodities for which national agricultural price policy is operative, there are several commodities which are grown in arid areas. These include pearlmillet, blackgram, greengram, moth, and mustard. Even wheat is grown wherever irrigation facilities are adequately available. By very definition of arid agriculture, farmers are able to harvest a satisfactory crop only in one out of three or four years. In such years, prices of these commodities, particularly during the peak marketing season, go below the support levels announced by the Government of India and situation warrants price support purchases by the public agencies. But, unlike rice and wheat in regular surplus producing areas (of Punjab, Haryana, Western UP & A.P), the arrangements for support operations either do not exist or farmers have to agitate for quite some time and then only support operations commence. By that time, several farmers are compelled, by cash needs, to sell to private traders at lower prices. While the need for support operations in these areas is all the more acute (because such occasions arise in a year after a lapse of 3 to 4 years), the farmers of arid areas do not get benefit due to faulty planning.
4.2.7.69. Apart from the commodities covered under national price support policy, there are several commodities which are life-line of arid farmers, for which the provision of Market Intervention Scheme (MIS) of GOI exists but due to lack of prudent planning, full benefits of MIS do not reach the arid farmers. Such commodities are guar, cumin, coriander, fennel and fenugreek and should be included in MIS. The inter-year price fluctuations in these arid zone crops are relatively larger hence provision should be made to insulate farmers from abnormal price dips.

4.2.7.70. There are several other commodities and products of arid zone which have special geographical indications, and considerable demand in distant markets, including overseas markets. These include sojat ki mehandi, kair, sangari, bikaneri bhujia, isabgol etc, which have considerable potential of increasing employment and income through branding and organised marketing and this requires (i) working capital support to farmers, (ii) modern terminal markets, (iii) strong market information system, (iv) branding and publicity and (v) organized, transparent and professional markets. After careful market research, special market plans and facilities should be created for these specialty products. Following the NDDB pattern, SAFAL type (as in Bangalore) venture should be established in Western Rajasthan, to begin with. Considering that forward linkages of production with value addition and marketing is the most crucial step in the end-to-end approach, the venture should be allocated the necessary financial support (nearly Rs.75 crores) for one 100-acre modern terminal market. The pay off from such an investment will be high, estimated at least 15 % IRR, not only in financial terms but also in social terms through increased employment opportunities and greater access to nutritive and high quality products.

4.2.7.71. Notwithstanding the recommendations contained in the Chapter on Marketing of this Report, the following strategies for strengthening production and marketing linkages in arid zone should be followed:

- Increase public investment in marketing infrastructure like rural roads, small rural storage godowns, cold chains and processing units. Relax
viability norms and provide tax and other incentives to private investors to invest in arid areas.

- Modern Transactional Banking in villages or in cluster of villages. The village knowledge centres must play key role in collecting and disseminating market and price information on relevant commodities.

- Adopt the revised APMC Act and amend State Agricultural Produce Marketing Acts to encourage private investment in agricultural marketing and contract farming arrangements.

- **Effectively implement price support policy in arid areas.** Instruments of advance planning and preparation for price support operations should be put in place at the State level.

- **Market Intervention Scheme for arid areas should be prudently formulated and implemented.** Both Central Government and States have a role.

- The role and functions of State Agricultural Marketing Boards and Agricultural Produce Market Committees should be redefined to include promotion of marketing organizations/contract – marketing arrangements of products specific to arid areas.

- **Agricultural marketing system research should be made a part of priority research under NARS for arid areas.**

- **Special commodity parks/zones** recently announced by the Government for arid-zone specific commodities should be put in place and made functional as early as possible.

- Extension agencies and NGOs must give emphasis on training of farmers in post-harvest operations, group marketing, packaging and branding at farm/village level and quality maintenance; enhancing quality and trade literacy.

- Develop **periodic markets** and increasing numbers of farmers’ markets and provide grading, sorting, standardization facilities in villages.
4.2.8.0 Financial Implications

4.2.8.1 A National Agriculture Risk Fund, as an institutional lifesaving support, is required to be set up by the Central Government for providing relief to the farmers in the event of successive droughts commonly experienced in Arid Agro-Ecosystems. Given the Poor economic condition of the farmers, many of whom are acutely stressed, Special Insurance Products, combined with Special Dispensation Mechanism, will be required to insulate the farmers from the high risk situation in arid zones. The Government of India may meet 50 per cent of the cost. The State Governments are called upon to provide Micro Capital Grants to SHGs, SFEs and other such groups to strengthen their capacities for backward and forward linkages in the production–processing-marketing chain, as initiated in Gujarat. The Central Government will be required to establish a Special Market Intervention Scheme for supporting prices of specialty products of arid zones in the year (once in 4 years or so) when the harvest is good. In order to bridge the serious gaps in marketing, a modern market centre will need to be established at a strategic place, preferably jointly by the Central and the concerned State Government.

4.2.8.2 In order to bridge the huge yield gaps and to capture new opportunities in productivity and income growth, increased financial resources will be needed for establishing advanced soil testing laboratories for addressing the micronutrient and other soil fertility imbalances, system-oriented on-farm demonstrations, supply of quality planting materials, promotion of “protected” (low cost greenhouse) production of high value commodities, strengthening of value addition and post harvest management and conservation of bio-diversity. Increased investment will also be required for establishing fodder, feed, grain and seed banks, training and capacity building at various levels, establishment of village knowledge centres and data bases. Additional financial resources will be required also for undertaking new researches and development of new technologies, new methods of extension and technology transfer such as the use of farm schools, traveling seminars, environmental costing and its realization etc. The Department of Agriculture and the ICAR of the
Ministry of Agriculture should provide part of the funds needed through re-ordering of priorities under their ongoing programmes.

An additional sum of Rs. 1,275 crore as detailed below, may be provided in the budget to cater to the above mentioned requirements (of which Rs.1075 crore to be provided by the GOI and the remaining Rs. 200 crore to be provided by State Governments) to implement the various activities during the next seven years, including the remaining two years of the current Five Year Plan and five years of the next Plan.

- A National Risk Fund ---- Rs.500 crore (GOI)
- Special Insurance Products and Dispensation --- Rs. 300 crore (GOI)
- Micro-Capital Grant to support drought proofing and to assist and mentor SHGs and SFEs ---Rs. 300 crore (State Government Rs. 200 crore and Central Government Rs.100 crore)
- Special Market Intervention Scheme ---Rs. 100 crore (GOI)
- Establishment of modern marketing centre --- Rs. 75 crore (GOI)
- Contingency fund--- Rs. 500 crore (GOI)*
- Strengthening horticulture-led diversification--- Rs. 300 crore (NHM)*
- Livestock *ex situ* germplasm conservation at Suratgarh Farm--- Rs. 100 crore (ICAR)*
- Augmenting water availability by promoting rainwater harvesting, groundwater recharge and water bodies restoration, development and management --- Rs. 250 crore *
- 2000 large scale demonstrations, establishment of 700 each of fodder, feed and grain banks, 1000 Farm Schools --- Rs. 300 crore *
- Soil health care based on soil test, including micronutrients analysis and popularization of agricultural machines and implements--- Rs. 200 crore*
- Commercialization of date palm production, support to micro-irrigation supply of quality vitroplants and other planting materials --- Rs. 120 crore*
* To be met through redeployment of resources from existing National Horticulture Mission and other National Missions, Watershed Projects, ATMA, ICAR’s KVK and other projects and by using National Rural Employment Guarantee Scheme and Food for Work Programmes.

Acknowledgement

The National Commission on Farmers is indebted to the ICAR, particularly the nodal point, CAZRI, for organizing the Experts Consultation on Arid Zone Agriculture on the 22\textsuperscript{nd} and 23\textsuperscript{rd} April, 2005 at Jodhpur. The Commission is also grateful to the Governments of Andhra Pradesh, Haryana, Karnataka, Jammu and Kashmir, Gujarat, and in particular to Rajasthan for deputing their experts and farmers to the consultation. The Commission also thanks the banks and financial institutions, other ICAR Institutions, State Agricultural Universities, NGOs, SHGs, Cooperatives, industries, etc., for their active participation. The valuable participation of farmers and their very useful contributions in this event are most gratefully acknowledged.
CHAPTER - 4.3

ENHANCING PRODUCTIVITY, PROFITABILITY, STABILITY AND SUSTAINABILITY

COASTAL ZONE AGRICULTURE

4.3.1 Our country is endowed with a long coastline of about 7,500 km of which the mainland accounts for 5,400 km, Lakshadweep coasts extend to 132 km and Andaman & Nicobar Islands have a coastline of about 1,900 km. Nearly 250 million people live within a distance of 50 km from the coast. The coastal zone is also endowed with a very wide range of coastal ecosystems like mangroves, coral reefs, sea grasses, salt marshes, sand dunes, estuaries, lagoons, etc., as well as with a rich diversity in both living and non-living resources. The coastal areas are assuming greater importance in recent years, owing to increasing human population, urbanization and accelerated developmental activities. These anthropogenic activities have put tremendous pressure on the fragile coastal environment and on marine biodiversity.

4.3.2 The coastal areas are subjected to frequent natural hazards. Some of the serious natural calamities in recent years are the super cyclone, which hit the Orissa coast in 1999 and the tsunami that occurred on 26 December, 2004. Along the coastal zone millions of farm and fisher families live and earn their livelihood. A Committee set up by the Ministry of Environment and Forests to review the coastal Regulations Zone Notification of 1991 under the Chairmanship of Prof M S Swaminathan has recommended that all development along coastal areas should be based on the principles of integrated coastal zone management, giving concurrent attention to the sea and land surface. India has nearly 2 million sq. km of sea surfaces available for economic use under the Exclusive Economic Zone of the UN Law of the Sea Convention. Unfortunately at present, coastal zone resources are being exploited in an unsustainable manner.

4.3.3 In chapter 3 on Fish for All in this report, we have recommended that an expert Committee may be set up to develop proposals for aquarian reforms on the lines of land reforms. The aim is to promote harmony between artesanl and mechanized fisheries on
the one hand, and agriculture and aquaculture on the other. We have also proposed the setting up of Fish for All Resource and Training Centres on the model of Krishi Vigyan Kendras for the purpose of imparting the latest technical skills to fisher women and men in all aspects of sustainable capture and culture fisheries. The training will cover the entire range of activities from capture or culture to consumption. This will help to avoid the growing conflicts between farmers and aquaculturists. We have also recommended Low External Input Sustainable Aquaculture (LEISA) in order to ensure that aquaculture can be practiced without ecological and social harm.

4.3.4 It would be useful to organise Women’s Aquaculture Estates along the coast through Women’s Development Corporations and financial institutions for the purpose of assisting dalit and fisherwomen to take to sustainable and profitable aquaculture. Seawater constitutes more than 97% of the available global water resources. In launching the Dandi March 75 years ago, Mahatma Gandhi wanted to stress that seawater should remain a social resource and should not be privatized either by Government or industry. In view of our long shoreline, it would be useful to initiate a programme on “Sea Water Farming for Coastal Area Prosperity”. Such a programme will involve the planting of mangroves, salicornia, atriplex and other halophytes. In the canals, shrimp/prawn farming can be undertaken. Such agro-aqua farms will generate considerable income and employment for coastal fisher and farm communities. We recommend the establishment of agro-aqua farms under the seawater farming project in about 50,000 ha in the States of Gujarat (Kutch), Maharashtra, Goa, Karnataka, Kerala, Tamil Nadu, Andhra Pradesh, Orissa and West Bengal. Coastal wastelands could be identified for this purpose. This kind of agro-forestry involving salt tolerant tree species and shrimp farming would provide additional livelihood opportunities which are very urgently needed in many coastal areas where considerable environmental damage is taking place due to increasing human population and unemployment.

4.3.5 The Sea Water Farming for Coastal Area Prosperity programme can be taken up in tsunami affected States with funds provided for rehabilitation. The planting of mangroves and other trees will confer both ecological and economic benefits. The
mangroves, casuarina and other tree species will serve as bio-shields, reducing the fury of cyclonic storms and tidal waves. Hence, we recommend that the Sea Water Farming for Coastal Area Prosperity Programme, based on sound scientific principles of agro-forestry may be given priority in the livelihood rehabilitation programmes being sponsored under the Prime Minister’s Relief Fund.

4.3.6 In the field of agriculture, rice cultivation is the predominant land use near coastal areas. The ground water resources are getting depleted and in some cases there is seawater intrusion in the aquifer. The data of the extent of ground water use in different coastal areas are given in table 1 below:

States, which still have a good untapped reservoir of groundwater near the sea, should use this invaluable resource very carefully.

4.3.7 Programmes should be developed for the conjunctive use of sea and fresh water. There is considerable potential for agro-forestry systems involving casuarina and several palms grown along with annual crops like arhar (pigeon pea). Already in many places casuarina, cashewnut and coconut are planted in a sequence from the shoreline. Unfortunately, research on coastal agriculture is very inadequate. There is need for
a Coastal Systems Research Programme (CSR) on the lines of Farming Systems Research Programme carried out in inland areas. Such a CSR programme should give concurrent attention to coastal agro-forestry, crop and animal husbandry and capture and culture fishings. **We recommend that ICAR may initiate an All India Coordinated Research Programme on coastal agriculture with the help of CSIR** (National Institute of Oceanography, Goa and the Central Salt and Marine Chemicals Research Institute, Bhavnagar) and State Agricultural / Animal Husbandry / Fisheries Universities. Currently fisheries research is fairly extensive, but coastal agriculture research is yet to receive the attention it needs.

4.3.8.0 The Coastal Zone Regulation Committee has recommended the following ground rules for management and sustainable use of coastal land and aquatic resources. We enclose these principles:

4.3.8.1 Ecological and cultural security, livelihood security and national security should be the cornerstones of an integrated coastal zone management policy.

4.3.8.2 The coastal zone would include an area from territorial limits (12 nautical miles), including its sea-bed to the administrative boundaries or the biological boundaries demarcated on the landward side of the sea coast. The coastal zone management should also include the inland tidal water bodies influenced by tidal action and the land area along such water bodies. This area should be taken up for an integrated, cohesive, multi-disciplinary and multi-sectoral coastal area management and regulatory system.

4.3.8.3 Regulation, education and social mobilization should be the three major components of a participatory and sustainable Coastal Zone Management strategy. Panchayati Raj institutions in coastal areas should be fully involved in the educational and social mobilization programmes.

4.3.8.4 Coastal regulation needs to be based on sound scientific and ecological principles and should safeguard both natural and cultural heritage. Heritage sites need particular
care and should be conserved in their pristine purity. These include areas of environmental significance, rich in biodiversity and scenic beauty. Bird sanctuaries, parks and breeding grounds of migratory birds should be protected.

4.3.8.5 **The precautionary approach** should be used where there are potential threats of serious or irreversible damage to ecologically fragile critical coastal systems and to living aquatic resources. Scientific uncertainty should not be used as an excuse for the unsustainable exploitation of coastal resources – both living and non-living.

4.3.8.6 Ecological economics should underpin economic activities, so that present day interests and future prospects are not antagonistic. Significant biological, cultural and natural assets should be considered incomparable, invaluable and irreplaceable and should receive overriding priority in the allocation of resources for coastal area protection and conservation

4.3.8.7 Coastal policy and regulations should be guided by the principles of gender and social equity as well as intra-generational and inter-generational equity, (i.e. the interests of future generations). They should be based on Mahatma Gandhi’s dictum, “Nature provides for everyone’s needs, but not for anyone’s greed”. All stakeholders should be involved in decision-making. Precious biological wealth, coming under Marine Biosphere Reserves, should be managed in a Trusteeship mode, with all the stakeholders protecting the unique natural wealth of biosphere reserves as Trustees and not as owners. A case study should be made on how the Gulf of Mannar Biosphere Trust is functioning, so that the Trusteeship pattern of sustainable management by the principal stakeholders can be replicated.

4.3.8.8 The regeneration of mangrove wetlands, coral reefs and sea grass beds as well as the promotion of coastal forestry and agro-forestry will confer both short and long term ecological and livelihood benefits. Carbon sequestration through coastal bio-shields will make an important contribution to promoting a balance between carbon emission and absorption, in addition to offering protection during coastal storms and calamities like
tsunami. An important lesson taught by the tsunami disaster is that the rehabilitation of degraded mangrove forests and the raising of coastal plantations of salicornia, casuarinas, Vetiver and appropriate species of halophytes will represent a “win-win” situation both for nature and coastal human habitations. No further time should be lost in initiating a national coastal bio-shield movement along the coasts of the mainland of India as well as islands. This can be a priority task under the National Rural Employment Guarantee and Food for Work Programmes.

4.3.8.9 The severe loss of life and livelihoods as well as property caused by tsunami in Andaman & Nicobar Islands and in the coastal regions of Tamil Nadu, Kerala, Andhra Pradesh and Pondicherry teaches us that short term commercial interests should not be allowed to undermine the ecological security of our coastal areas. Human memory tends to be short and neglecting the lessons of tsunami will be equivalent to writing off the future of coastal communities.

4.3.9 The prospects for sea level rise as a result of global warming and climate change are real. Therefore there is need for anticipatory research to meet the consequences of a rise in sea level to both agriculture and aquaculture. Integrated Coastal Zone Management will be possible only if there is convergence and synergy among numerous activities along the coast. Since several Ministries / Departments / Institutions are involved in the use of coastal land and water resources, it would be useful to set up a National Board for Coastal Agriculture under the Chairmanship of the Union Minister for Agriculture and Food in order to provide the coordination needed in policy formulation and task implementation in the area of coastal agriculture including capture and culture fisheries. Sustainable livelihoods have to be found for large numbers of landless labour families living along the coast if further damage to fragile coastal ecosystems is to be avoided. Also, we should harness seawater for sustainable tree farming and for fisheries.

4.3.10 Our coastal land and water resources can provide income and job security to millions of families living in coastal land areas provided we use them scientifically. Both
to benefit from this opportunity and to safeguard millions of children, women and men living along the coast from the fury of natural disasters like cyclones, storms and tsunamis, it is high time that we start initiating integrated and coordinated efforts to improve the productivity and profitability of fisheries, forestry and crop and animal husbandry along our 7,500 km coast line.

4.3.11 Integrated farming systems and the conjunctive use of sea and fresh water will open up new windows of livelihood opportunities for the 250 million people living in the coastal zone. We suggest that the proposed National Board for Coastal Agriculture (agriculture will cover crop and animal husbandry, fisheries and forestry) be set up soon. The Board should also have the Ministers in charge of Environment and Forests, Science and Technology, Ocean Development, Water Resources and Commerce and senior representatives from all the Coastal States and A & N and Lakshadweep Islands as Members, so that a holistic view on all aspects of sea water use and coastal agriculture management can be taken.
CHAPTER 4.4

ENHANCING PRODUCTIVITY, PROFITABILITY, STABILITY AND SUSTAINABILITY

MISSION FOR THE PROSPERITY OF SUGARCANE FARMERS

4.4.1.0 Sugarcane and Sugar Industries

4.4.1.1 Sugar industry is the second largest agro-based industry, next to textiles in India. However, it is by far the largest agro-based industry in rural areas. Nearly all other agro-based [large] industries are set up in urban areas. The sugar industry consists of two stages of production process- first, farm level sugarcane production and second processing of sugarcane into sugar. Sugarcane processing also generates valuable by-products, which are used in many downstream industries. There are 553 sugar mills in the country, out of which 453 were in operation during 2002-03. About 60% of the mills are in the cooperative sector, 35% in the private and 5% in the public sector. The sugar production during 2002-03 was 20.1 million ton as against 8.75 million ton in 1988-89.

4.4.1.2 Sugarcane cultivation, which is the first stage in the process of producing sugar, occupied around 4.30 million hectare in 2002-03 and produced 282 million ton of cane. Sugarcane occupies less than 2.5% of the total cultivated area and contributes nearly 7.5% gross value to the agricultural production in the country. About 4.5 million farmers grow sugarcane and a large number of agricultural labourers are involved in sugarcane cultivation, harvesting and other ancillary activities.

4.4.2.0 SWOT Analysis – Sugar Industry and Sugarcane Cultivation

4.4.2.1 Strengths

4.4.2.1.1 India is the second largest producer of sugar in the world after Brazil. During 2000-01 to 2002-03, India’s share in cane sugar production was around 15%. The industry has enabled the country to be self-reliant in this highly sensitive essential commodity of mass consumption. During the last three years, India exported about 4 million tons of sugar. The sugar industry pays well over Rs 10,000 crore to the sugarcane growers every year for cane, about Rs 1600 crore by way to excise duty and about Rs 600 crore as purchase tax and cess on cane. The total value of sugar produced is around Rs 24,000 crore. The sugar industry provides direct employment to nearly 0.5 million
workers, and a host of others gain employment in industries, which use its by-products as their raw material. Molasses, a by-product of the sugar industry is the main raw material for alcohol and alcohol-based industries. In India, a total of 290 distilleries with an installed capacity of about 3200 million litres are functioning; out of these, 107 distilleries are attached to the sugar factories themselves. Sugarcane bagasse is an important source of power in the sugar mills. Bagasse is also being used as raw material for paper industry. Another by-product, the press mud, contains plant nutrient and could be an important source of organic manure for the crops. The sugar factories, particularly the cooperative sugar factories have been the focal point for socio-economic development in the rural areas by mobilising rural resources, generating employment and higher incomes, transport and communication facilities. Further, many sugar factories have established schools, colleges, medical centres etc for the benefit of the rural populations in the area which have long-term productivity consequences.

4.4.2.1.2 Sugarcane is the only raw material for all the major sweeteners produced in India. Besides the sugar factories and other industries based on the by-products of these factories, sugarcane also supports rural and cottage industries, viz. gur [jaggery] and khandseri industries which together produce about 10 million tons of sweeteners.

4.4.2.1.3 Sugarcane is more profitable relative to other crops in the area where it is planted.

4.4.2.3.0 Weaknesses

4.4.2.3.1 The health of the sugar industry is not good and it is facing problem in attracting fresh capital. The sugar mills often find it difficult to pay for the sugarcane supplied by the farmers on time. The large and surplus production in recent years and the limitation of storage space and the costs involved had aggravated the problems. Obsolescence of technology and machinery is another factor along with unsustainable low installed capacity of many factories. Over 40% of the factories are reported to be more than 40 years old. In many of these factories mechanical breakdowns are more than normal, fuel consumption is much higher and extraction rate is low. Poor management [lack of professionalism particularly in the cooperative and public sector units] and diversion of funds are the other weaknesses of the sugar industry. Short crushing season and lack of development of alternative feed stock are other issues, which need attention.
4.4.2.3.2 The major problem of the sugarcane cultivation is the stagnation/decline in the average yield over the years. An average all India yield of above 66MT/ha was achieved in 1991-92 where as in 2002-03 it was 64.6MT/ha. The highest average yield during the last 12 years was obtained in 1994-95 at 71.3MT/ha and more or less similar average yields were obtained in 1998-99 [71.2MT/ha] and 1997-98 [71.1MT/ha]. However, since 1998-99, the average yield has continuously declined. The reasons for the stagnancy/decline are discussed subsequently.

4.4.2.3.3 The mismatch between cane production and demand from the sugar factories is another issue. Over time, the growth rates in cane crushing capacity, quantity of cane crushed and sugar production has outstripped the same in terms of area under cane, its yield rate and total production. Thus, a situation of general cane shortage has been created, leading to competitive bidding up of the price of cane, which is the major item of cost in the production of sugar. The problem was compounded by the decline in sugar prices during 2001-02 to 2003-04 causing serious financial problems to the sugar industries and the sugarcane growers due to mordinate delay in payment of cane prices.

4.4.2.4.0 Opportunities

4.4.2.4.1 The silver lining for the sugar industry in India is the rapid growth in the per capita consumption of sugar, the rate of growth in population and the fact that the consumption of sugar as a proportion of total consumption of sweeteners viz. sugar, gur and khandseri is also increasing. Based on the growth trends, the average per capita consumption of sugar in India is estimated to increase from the level of 18.3 kg per year in 2001-02 to 23-24 kg by 2010. Even on the basis of an average consumption of 21 kg
per year and the projected population 1.16 billion by 2010, the total demand of sugar is estimated to increase to 24.3 million tons. Further, the domestic prices of sugar during the last about a year or so have also firmed up. Another important opportunity for the sugar industry is the potential of its by-products particularly molasses for manufacture of ‘ethanol’. Based on the research findings, up to about 20% ethanol could be blended with petrol even without any change in engine design and carburetor. Ethanol is not only eco-friendly, but could also be foreign exchange saver for India. This is becoming more relevant by the day with increasing international prices of crude. It is also possible to have car engines totally run on alcohol, as in Brazil, which could further save the consumption of petrol. There is also considerable potential for production of many value added products from cane juice and also developing full potential of production of green fuel from bagasse.

4.4.2.4.2 On sugarcane production, the major opportunities are the large potential to increase the productivity of cane and also the sugar recovery levels. As per the agro biological calculation and considering 50% use of solar radiation and 30% transpiration loss in sugarcane, it is considered possible to have a yield of 600Mt/ha [based on a paper submitted by the Vasantdada Sugar Institute, Pune]. Some of the progressive farmers in Maharashtra have achieved 350MT/ha yield. The following table shows

Table 2: Yield position and potential of sugarcane

</tbody>
</table>

[Based on information provided by the Vasantdada Sugar Institute, Pune]

4.4.2.4.3 This is further strengthened from the fact that the average yield in Tamil Nadu was 101.6MT/ha in 2001-02 and 106.8MT/ha in 2002-03, even Karnataka had achieved average yield of above 81MT/ha in the above years. The potential to improve average recovery level is also there, with Maharashtra consistently achieving well over 11%
recovery for last about 8 years and Karnataka well over 10.5% during the last 4 years against the all India recovery of around 10.3% during 2001-02 & 2002-03. The above shows that technology and do-how does exist in India to achieve a much higher level of productivity and quality of sugarcane production, the need however is to make well planned concerted efforts in this direction.

4.4.2.5.0 Threats

4.4.2.5.1. Sugar is probably the most distorted among agricultural products in the global market mainly due to policy distortions in some major developed countries like the U.S, Japan, EU etc. which has kept the global demand much lower. It not merely affects the export demand of Indian sugar, but also creates problems due to possibility of cheaper imports. Other important issues for the sugar industry are the aspects relating to the pricing of the sugarcane. If the cost of sugar is to be brought down in a regime of free global trade, pragmatic policies need to be evolved through mutual consultations with the stakeholders involved in the supply of the three major inputs i.e., the sugarcane, interest on bank credit and the labour costs which contribute about 90% of the cost of production of sugar.

4.4.2.5.2 The threats to sugarcane cultivation mainly arise from the weaknesses and threats to the sugar industry as the fortunes of the sugarcane farmers are closely linked with the sugar factory/ processing unit in the area. The prospects of expansion in sugarcane area are now extremely limited due to the high water requirements and the claims of the other crops. Further, sugarcane being a soil nutrient exhausting crop, the farmers have to plan crop rotations and also take care of the soil health for sustainable production

4.4.2.6.0 Sugarcane Cultivation - The Developments

4.4.2.6.1 There has been in the past a steady growth in area under sugarcane cultivation. The area under sugarcane was only 17.07 lakh hectares in 1950-51 which increased to 44.3 lakh hectare in 2001-02. It declined to 43.6 lakh hectare in 2002-03. Since there are year-to-year fluctuations in the area under sugarcane.
Table 3: Area under sugarcane (averages for five years –1966 to 2002)

</tr>
</tbody>
</table>

4.4.2.6.2 The area has increased by nearly 69% in 30 years. The average increase in every five years has been around 9%. However, the area under sugarcane to the total cropped area has remained more or less constant at about less than 2.5%. Sugarcane is also considered to be most profitable among the major crops in India. The possibilities of similar increases in the sugarcane area in future are however is extremely low due to competition from other crops and the soil and water requirements.

4.4.2.6.3 Nearly 92% of the sugarcane is cultivated in irrigated conditions. While in the sub-tropics 6-8 irrigations may be sufficient, in the tropical regions the sugarcane crop requires 16-18 irrigations.

4.4.2.6.4 Sugarcane is generally grown in all States in India excepting the hill States. However, ten States had more than 1 Lakh hectare under sugarcane during 2002-03 accounting for nearly 96% of the total sugarcane cultivating area in the country.

The above data shows that the yield in tropical area States is higher than the sub-tropical States. The highest yield per hectare in 2002-03, was observed in Tamil Nadu [106.8 M.T./ha] followed by Karnataka [84.4 M.T./ha], Gujarat [69.4 M.T./ha], Andhra Pradesh [65.8 M.T./ha], Maharashtra [61.8 M.T./ha]. It is worth noting that the yields in Andhra Pradesh and Maharashtra during 2001-02 were 82.9 M.T./ha and 78.1 M.T./ha respectively and the decline during 2002-03 was mainly because of drought conditions and the pest attack in Maharashtra. As against the above, the yield among the sub-tropical States during 2002-03 was highest in UP [62.8 M.T./ha] followed by Punjab [60.3 M.T./ha], Uttranchal [59.3 M.T./ha], Haryana [44.4 M.T./ha] and Bihar [24.6 M.T./ha].

4.4.2.6.5 The recovery rates were highest in Maharashtra [11.64] followed by Karnataka [10.79] and Gujarat [10.58]. The recovery rates were also good in Haryana [10.13], Andhra Pradesh [10.10] and Tamil Nadu [9.88]. The lowest recovery rates were in Bihar at about 9%.

4.4.2.6.6 A worrisome aspect is the stagnation in all India average over the years and continuous decline of average yield over the last five years.

4.4.2.6.7 As stated earlier, with anticipated increase in population to 1.16 billion and the per capita consumption of 21 kg, by 2010, the requirement of sugar in India would be about 24.36 million tons. Keeping in view that increase in area under sugarcane may be extremely difficult to achieve [in the context of other crops], it would be necessary to increase the yield to atleast 80 M.T./ha and recovery from the present level of 10.36% to 11% by the end of 2010-11 to have sugar production of around 25 million ton to take care of the projected increase in demand.

4.4.2.6.8 Two aspects of sugarcane production which impact the average yields but are often ignored are the ‘ratoon’ and ‘adsali’ crops. Ratooning of crop is a common practice [around 40% of the total cane produced is through ratoon crop], it is more prevalent in UP where over 50% of the sugarcane production is from ratoon crop. Ratooning brings down the cost of production and leads to early maturing which helps the factories to start early. However, the yield under the ‘ratoon’ crop is lower than the plantation crop. This partly explains the low average yield in UP. In fact, the farmers generally neglect the ratoon crop, which brings the yield down. With integrated ratoon management, maintaining required plant population through gap filling by settlings, use of adequate fertilizers and need based micro-nutrients, better irrigation management, plant protection care etc. training of the farmers and more intensive extension work by the extension staff and the sugar factories is called for higher yields from ratoon crops could be taken. Maharashtra has large areas under the ‘Adsali’ crop, which is grown over a period of 15-18 months. The yield under this crop is higher than the other crops by about 30-35%. In Maharashtra around 20% area is covered by Adsali, which improves the overall average yield figures of Maharashtra.

4.4.2.6.9 The main reasons for recent decline in sugarcane yield are the weather conditions, attack of ‘white woolly’ aphid in Karnataka, Maharashtra etc. and delayed
cane payments in certain areas which led to constraints in use of desired quantity and quality of inputs. The other constraints leading to lack of improvement in productivity are as under:

(a) Inadequate care of the ratoon crop and constraints in adequate availability of quality planting material.

(b) Depletion of micro - nutrients from soil due to monoculture and unbalanced application of major nutrients.

(c) Depletion of organic carbon in the soil due to gradual shift towards application of mainly inorganic fertilizers.

(d) Low adoption of available technologies for increased production and productivity.

(e) Inadequate research/extension efforts in developing/adopting location specific varieties and development of superior varieties with high cane yield and high sugar content with resistance to biotic and abiotic stress for different regions.

(f) Inadequate efforts for identification of varieties with high input use efficiency in terms of water requirement, micro-nutrients, sunlight and varieties suited to low input conditions.

(g) Inadequate attention to use of crop residue from sugarcane and sugarcane industry by-products such as press mud, sugarcane trash and distillery effluents.

(h) Inadequate attention to tissue culture.

(i) Problems in timely and adequate availability of quality inputs including credit.

(j) Inadequate attention to development and dissemination of information regarding better farm appliances/equipments for harvesting, ploughing, planting etc.

(k) Poor drainage in some areas.

(l) Lack of adequate participation of the sugar factories in the development of sugarcane.

A cane development department with adequate and competent staff is essential for each sugar factory.

4.4.2.7.0 Issues Concerning Sugarcane Growers

4.4.2.7.1 Sugarcane is a perishable crop. It has large bulk with an average all India yield of nearly 65 tons per hectare in 2002-03. Further, the sucrose content in sugarcane declines if it is not crushed quickly after the harvest. The above factors make it prohibitive for farmers to carry their crop to any distance. Around 90% of the sugarcane
is crushed for making sugar/khandseri/gur/jaggery etc. By and large, therefore the growers are tied up with the sugar factories/other processing units. The sugar factories also require firm arrangements for supply of sugarcane. The practices regarding sugarcane area reservation, the pricing and marketing tie up etc. peculiar to sugarcane cultivation which impact the growers are discussed in the following paragraphs.

**Cane Area Reservation**

4.4.2.7.2 Sugarcane is an essential commodity under the Essential Commodity Act, 1955; as such the Government is empowered to control its production, distribution and supply. The Government regulates its supply to sugar factories under the Sugarcane [Control] Order, 1966. The power of regulation of cane supplies has been delegated to the State Governments. Under the above order, the Government is empowered to reserve area for a factory having regard to the crushing capacity of the factory, the availability of sugarcane in the reserved area and the need for production of sugar with a view to enabling the factory to purchase the quantity of sugarcane required by it. The cane growers in the reserved area are required to enter into bond with the sugar factory for supply of a specified quantity or percentage of sugarcane grown by him/her. The grower is not allowed to supply cane to any factory outside the reserved area unless he/she obtains a permit for this purpose. The factory is also under an obligation to crush the entire cane, which is bonded by the growers.

The benefits of reservation are:

- It controls the cost of transportation and loses of sucrose due to the time taken in taking it to factories located at a distance.
- It helps the factories to regulate the cane supply according to the crushing capacity available each day. In absence of such an arrangement, the factory may have inadequate supplies of sugarcane on certain occasions, while on other days, the supply may far exceed the capacity. The mills in this situation may have to install higher capacities to crush all the sugarcane which may be supplied during the peak season which would lead to higher cost of production or alternatively the growers may have to wait with the cane which in turn would lead to reduction in sucrose contents.
- Helps in building linkages between the mills and the growers.
- Encourages the mills to take up cane development work.
- Helps the banks to link credit with marketing.

4.4.2.7.3 However, if the factory refuses registration or bonding or is unable to crush sugarcane within the normal season or within 15 days after the normal season, the grower is permitted to supply the cane to another factory. On the other hand, during the period of cane shortage poaching of sugarcane becomes a serious problem. Though the State Governments impose penalty for poaching, unless it is adequate it does not serve as a deterrent to the factories. In Punjab, for example, the penalty on conviction in a court was only Rs. 2000, which was grossly inadequate. This needs a review by the State Governments.

4.4.2.7.4 Further, the reservation of area needs to be on a long-term basis say, 5 to 10 years with provision for review by the State Government to ensure better linkages between the grower and the factory. The second appeal in the case of dispute could be to the Government of India. There could be a system of social audit which could also facilitate decision making in case of disputes. In UP, the area reservation is for one season at a time which is not conducive to orderly cane development work. Long-term reservation provides the necessary incentive to the factory to undertake the development work in its reserved area. This also encourages building of long-term credit arrangements with the banks. Issue of reservation order of long-term periodicity was also favoured by the Standing Committee of the Lok Sabha on Food, Civil Supplies and Public Distribution (1995-96), as well as by the high Powered Committee on Sugar Industry under the Chairmanship of Shri Mahajan [1998]. Further, it is also important that the reservation of area is done systematically and is conducive to efficient functioning of the mills. There are instances where the villages allotted to different sugar mills are interspersed. This needs to be corrected in consultation with the factories/growers.

**Cane Pricing**

4.4.2.7.5 Sugarcane accounts for more than 60% of the cost of production of sugar. The Central Government fixes a Statutory Minimum Price [SMP] in terms of Clause 3 of Sugarcane (Control) Order 1966 with regard to the:
- Cost of production of sugarcane.
Return to the grower from the alternate crop and the general trend of agriculture commodities prices.

Availability of sugar at reasonable prices to the consumer.

The price at which sugar produced from sugarcane is sold by the producer of sugar;

Recovery of sugar from the cane.

The Commission for Agricultural Costs and Prices [CACP] while recommending the SMP also takes into account other factors such as current realization from sugar sale, the demand and supply situation, level of sugar stocks, cost of transportation, international price situation and the need for stability in sugarcane production. Further, according to the law, the farmer is also entitled to an additional payment out of price realization by the factories (Clause 5 A of the Sugarcane Control Order, 1966). The sharing formula which is commonly known as ‘Bhargava Formula’ \([(R-L)/2]\) has been discussed subsequently.

**Table 6: Increase in SMP**

</tbody>
</table>

* [The SMP for 1999-2000 was Rs. 56.10 per qtl.]

For the year 2004-05, the CACP had recommended that the SMP for sugarcane payable by the sugar factories be fixed at Rs. 74.50 per quintal linked to be basic recovery of 8.5% subject to a premium of Rs. 0.88 for every 0.1% point increase in the recovery above that level. At All India average recovery rate of 10.29%, the SMP recommended worked out to Rs. 90.25 per quintal. The CACP also recommended that the SMP needs to be announced by the Government at least one year in advance to give the price signals, the delayed announcement of SMP did not serve any purpose in providing price signals to the growers to help in matters relating
to allocation of land and other resources. If the SMP could be announced for a longer period say about 3 years, it would help in better planning and stabilizing cane production. The feasibility of such announcement could be examined by the CACP. While the SMP has been steadily increasing, the sugar prices during the last 4-5 years upto 2002-03 had been rather low. **Table 7: Sugar prices –1999 to 2003**

</tbody>
</table>

The situation started improving rather slowly during 2003-04 and the prices firmed up in 2004-05. The SMP needs to carefully balance the interests of the growers and the factories. While the sugar prices were declining, the SMP for sugarcane continued to increase which also contributed towards increasing the sugarcane price payment arrears [discussed later.] leading to an unsustainable situation. Some of the other important issues connected with SMP are discussed in the following paragraphs:

**Fixation of SMP on Regional Basis**

4.4.2.7.7 The sugar industry has been suggesting that the SMP needed to be fixed on a regional basis- one for the tropical region i.e., Maharashtra, AP, Tamil Nadu, Karnataka, Orissa & Gujarat and the other for the sub-tropical region covering states of UP, Punjab, Haryana, Bihar, Uttarakhand, Rajasthan and MP. The suggestion for regional SMP is mainly because [a] the yield of sugarcane is higher in the tropical region as compared to sub-tropical region and hence the cost of cultivation is lower [b] the sales realization from free sale sugar in sub-tropical region by factories is higher than the tropical region and the variation is large ranging from Rs. 44 to Rs. 110 per quintal.

While it is true that the cost of cultivation as well as the realization from free sugar sales is lower in tropical region, fixation of SMP on a regional basis would be against the fixation of support price of all other agricultural commodities which is on a
national basis. Further, the cost of cultivation differs within the tropical and sub-tropical regions as also within the State, under the circumstances it may lead to many other similar demands. In any case, the region which is more suitable than the other [has a lower cost of production] should get the price benefit for expanding and growing. Further, such regional SMP would not be in line with the developments in the markets which are getting integrated at national and the international level.

**Raising the Base Recovery Rate from the Present 8.5%**

4.4.2.7.8 Upto 1971-72 [sugar season], the base recovery level was taken at 9.4%. On the recommendation of the Agriculture Price Commission to reduce the base recovery level to 9%, the Government decided to reduce it to 8.5% which continues since then. The All India recovery level has been improving and was 10.32% in 2001-02. Keeping in view the above, as also the interest of the farmers, there is a need to increase the base level recovery. It is understood that the CACP has also suggested for 2005-06 that the base recovery level may be fixed at 9%. The factories having a lower average recovery [for the season] may have to improve their cane development efforts including the cane collection arrangement and the operational efficiency. Improving the recovery rate benefits the farmers as they get higher price for their produce and it also leave a surplus to the factory as it has higher production and hence higher income by sale of sugar etc.

4.4.2.7.9 There is also a suggestion to link the sugarcane price to the sucrose contents of the cane as is done in some other countries. While this may be a better strategy to encourage the farmers to grow better varieties, this could be done only after satisfactory arrangements for assessing sucrose contents of the cane could be tested and become generally acceptable. This however needs to be expedited and done in a time bound manner. Under the circumstances, for the time being existing arrangements may have to continue. However, it may be possible even now to fix incentive prices for varieties, which have higher sucrose contents with a view to encourage the farmers to take up cultivation of these varieties.

**The State Advised Price**

4.4.2.7.10 Some of the State Governments have been fixing the sugarcane prices commonly known as the State Advised Prices [SAPs]. Unfortunately, there is a
normal tendency on the part of the State Governments to raise the prices, which could even become uneconomic for the sugar factories. According to the Mahajan Committee Report [1998], “This tendency may get accentuated in the era of unstable and coalition Governments where short-term consideration of political expediency may outweigh consideration of the long-term impact on the sugar industry in the State and consequently in the long-term, interest of the cane growers themselves. There is also some sort of competition among the States for announcing higher cane prices than the other and this tendency is likely to be accentuated.”

4.4.2.7.11 A connected issue is the general apprehension of the growers that the clause 3 of the Sugarcane [Control] Order, 1966 which indicates the aspects to be considered for fixation of the SMP includes among other two clauses which tend to influence in favour of fixing of lower prices of sugarcane. These clauses are [a] availability of sugar to the consumers at a fair price and [b] sugar producers sell price at which sugar produced from sugarcane. Deletion of these two clauses would mean that the common unmerited perception about the cane prices deliberately being fixed lower to keep the levy price lower for PDS purposes would be generally laid to rest. Incidentally, the clause 5A of the Sugarcane Order 1966, which states that the farmer is entitled to an additional payment out of the price realization by the factories, has implementation problems. Under this formula [Bhargava Formula], the farmers and the mills share the excess realization broadly in the ratio of 1:1. The sharing formula is: \[
\frac{R-L}{2}.
\]
Under this, R is the realization from the sale of sugar [levy and free] and L is the unit cost of production. However, there have been considerable delays in the notification of the Zone-wise ‘L’ factor by the Govt. of India and factory-wise additional sugarcane price to be determined by the State Government. The ‘L’ factor for four season was announced in February 2003 and for 2001-02, the ‘L’ factor was announced on 6 April, 2005. Information regarding announcement of cane price by the State Government on the basis of above details is also not available raising doubts about the effectiveness of the implementation of the above clause. Prima facie the formula appears to be in order save for the implementation delays. If it could be announced quickly at the end of the season, the impact would be much better. A connected question however is as to why the farmer should not have a share in the
value of the byproducts of the factory, which are sugarcane based. The problems of sugarcane pricing are serious. A continuous upward movement of the sugarcane prices without any relationship with the price of sugar is not sustainable. It is welcome that the Government of India have constituted an Expert Group on New Sugarcane Pricing Policy. It is hoped that the new pricing policy would serve the interests of the growers and the factories in a more equitable manner and to the satisfaction of all concerned.

**Delayed Payment and Cane Arrears**

4.4.2.7.12 It is not only necessary to ensure remunerative price for the produce, but it is also important that the farmers are paid the price promptly. The farmers cite long delays in payment of sugarcane prices by the sugar factories as a major reason for less than the optimum level of input usages leading to low productivity. The Govt. of India have amended the Sugarcane [Control] Order, 1966 evaluating the Central Govt./State Government/Officers authorized by the Central Govt./State Governments to recover the arrears of cane prices remaining unpaid after 14 days supply of sugarcane by the growers, together with interest @ 15% per annum thereon, as arrears of land revenue. However, in practice there is considerable delay in making the payment to growers. There have been agitations/demonstrations regarding arrears in cane price payment and it has often become an issue taken up by political parties. The cane arrears on 30.04.04 were reportedly Rs. 2568 crore mainly due to poor sugar prices during the last 2-3 years and accumulation of sugar stocks with the factories. Due to the stringent provisions against delay in cane payments, the factories do want to avoid the delays but financial constraints often make it extremely difficult for them. In view of the high build up of cane arrears, the Govt. of India decided to create a buffer stock of 2 million tons of sugar for one year in December 2003 (subsequently extended by one more year). Further, the Government also announced two packages of special assistance to the State Governments. A sum of Rs. 678.06 crore was allocated as a one time assistance to the Governments of UP, Uttranchal, Bihar, Punjab and Haryana to help clearance of sugarcane price arrears for 2002-03 by private sugar factories subject to the following conditions: -
(a) It would cover difference between the SAP and SMP with regard to the sugar factories in the private sector only.
(b) The assistance would be in the nature of a soft loan at a concessional rate of interest of 4% p.a. with an initial moratorium of 3 years and repayable in 3 years thereafter.
(c) The assistance would be contingent upon the State Government undertaking not to declare SAP in future either formally or informally.
(d) The money would be released to the farmers directly by the District Officials.

In addition, the Government of India also provided a one-time assistance to the State Government by permitting them to raise additional market borrowings to the used for liquidating the cane price arrears of the mills in the cooperative and public sector in the States where SAPs were announced and all mills in States where the practice of SAP announcement did not exist. The conditionality of assistance were broadly similar to the first scheme with moratorium of 5 years and repayment in next 5 years of loans extended by the State Governments to the factories. As a result of the above schemes, the arrears as on 30.09.2004 came down from Rs. 2568 crore [30.04.04] to Rs. 560 crore. During 1992 to 1997 the peak level arrears formed nearly 20% of the total cane payment. The arrears in 2004 had formed nearly 30% of the total cane payment. The cane payment arrears have generally been lower in the case of cooperative sugar factories and rather high in the case of public sector units. Strict enforcement of law regarding timely payment of sugarcane price to the growers is called for.

**Cane Supply Arrangements**

4.4.2.7.13 Cane supply arrangements are extremely important both for the growers and the sugar factory. Sugarcane is perishable and the sucrose contents get reduced if it is not milled within a short period after harvesting. For the factory it is important that it gets adequate supplies of cane for as long a period as possible to increase the crushing season and also within the least possible time after the harvest. The growers are also interested to supply their sugarcane soon after maturity to get the income as well as time to prepare the land for the next crop. Different varieties of cane reach their optimum sucrose content at varying period. There is therefore need for considerable planning regarding the timing/varieties etc. planted in the factory area and also in managing the flow of cane
supplies. The factory wants a planned inflow of cane as per its installed capacity. Since a large number of farmers [normally about 10,000 to 15,000 farmers] supply the sugarcane to each factory in about 150 to 180 days a very careful planning and fine-tuning is necessary to complete the operations efficiently for the maximum benefit of the farmers and the factory.

4.4.2.7.14 As already stated, the State Governments reserve the area for various sugar mills in the State. However, the practices regarding cane supply vary considerably in the States. The major cane producing States could be divided into three groups regarding the sugarcane/supply arrangements. Maharashtra & Gujarat have a similar system, the tropical States of Tamil Nadu, Andhra Pradesh & Karnataka follow another system and the sub-tropical States i.e., UP, Bihar, Punjab & Haryana have a different system.

4.4.2.7.15 In Maharashtra, Gujarat and some parts of north Karnataka, the growers supply cane ex-field to the factory and the sugar factories [which are mostly organized as co-operatives] arrange for the harvest and transportation of the sugarcane. The harvesting in this arrangement is obviously planned by the sugar factory as per its requirements and the crop in the area based on variety/maturity etc. The factories engage harvesting/transporting groups/contractors who handle the entire operations. Many of the factories own carts/trolleys etc., which are used for transportation of the cane. The operations are smooth and save the growers from organizing harvesting and transportation frequently to dispose off the entire produce. However, the State Governments/CACP may examine it whether certain norms could be developed for harvests and transportation costs and cap be fixed.

4.4.2.7.16 In Tamil Nadu and Andhra Pradesh, the factories have been assigned area on long-term basis. This has encouraged the factories to take up cane development work more seriously, leading to better yields and recovery rates. The growers handle the harvesting and transportation. The direct relationship between the grower and the factory has an overall good impact on cane cultivation and development. There are no outstation procurement centers unlike in sub-tropical regions, which lead to delays and consequently poor recovery percentage. The factories bear transport cost upto a certain radius and the balance is borne by the grower.
4.4.2.7.17 In UP, which has nearly 45% of the sugarcane growing area of the country, the area reservation is done for one season at a time and the factories are also asked to open and operate cane purchase centers. In some cases, the factories operate as many as 100 purchase centers. The sugarcane is purchased through the Cane Cooperative Societies and the sugar factory does not have direct relationship with the grower. The payments for the cane are also made through these societies. These societies enter into agreement with the factory regarding the supply of cane. Under this arrangement, the sugarcane is harvested by the grower and supplied at the purchase center/factory gate. The factory meets the cost of transportation from the purchase center to the factory. The Cane Cooperative Societies prepare supply calendar and issue supply slips [Parchies] to the growers. These supply
slips are issued on the basis of the last 2-3 years supplies of sugarcane. The quota of a farmer is divided in the expected days of running of the sugar factory and he/she is issued supply slips in equitable proportion. As the supply entitlements are fixed on the basis of last 2-3 years supply, the farmers are reluctant to introduce better varieties, which could increase the yield due to anticipated difficulties in selling the excess production. The factories indicate their daily requirement of cane separately for supplies at the Gate [Factory] and at the purchasing centers. Weightment both at the Factory Gate as well as the Purchase Centre is expected to be done in the presence of the representative of the Cane Grower Cooperative Society. However, of late, due to staff constraint, the cane Grower’s Cooperative Societies are often unable to send their representatives for the weighing. The farmers do apprehend that the weightment may not be correct and would like electronic weighing scales to be installed at all places. Further, the sugarcane growers also complain about the long waiting period at purchase centers. The arrangement is complicated. It also leads to delay in reaching the cane to the factory and consequent decline in recovery percentage. The farmers engage harvesting teams and have to harvest their field repeatedly. The system is not farmer friendly. The system is also not effective linkages between the sugarcane growers and the factories.

4.4.2.7.18 The arrangement in Punjab and Haryana is similar to UP excepting that the cane is supplied by the farmers directly to the factory. In Bihar Cane Cooperatives are working in certain areas where the cane is routed through these societies but elsewhere it is direct to the factory.

4.4.2.7.19 The system of purchase of sugarcane by factories through the Cane Cooperative Union has been considered to be less efficient as compared to the direct linkage of farmers with the factories. Since the sugar factories have mostly computerized preparation of cane supply calendars, issuing supply-slips to the farmers and maintenance of farmer wise records etc. the role of the cane cooperatives has dwindled. Further, the farmers also complain about red-tapism in the cane cooperatives. The Lok Sabha Standing committee on Civil Supplies & Distribution [1995-96] recommended direct link between the farmers and the factories. The Tuteja committee on Revitalization of Sugar Factories [2004] also favoured direct tie up of farmers with the factories and a tri-partite agreement between the banks, farmers and factories. The compulsory routing of the
sugarcane supplies through the Cane Union needs a review. To began with UP could consider trying the direct linkage of the sugar factories and growers at least on a pilot basis and evaluate the same.

4.4.2.7.20 The factories need to have a well planned programme of crushing with respect to different varieties of cane grown in their reserved area. The farmers growing early varieties and ratoon should be able to harvest their cane early so that they get the benefit of switching over to these varieties. The issue of supply slips should be strictly on the basis of maturity of crop and planning dates.

4.4.2.8.0 OTHER ISSUES

Khandseri & Gur
4.4.2.8.1 Khandseri and gur provide traditional sweeteners at lower prices than the white sugar and also an outlet for disposal of cane to the growers in areas where sugar mills are not operating or do not have enough capacity to crush the entire cane production. The use of sugarcane for gur and khandseri has come down from about 55% in 1980-81 to 28.9% in 1999-2000. Among the major sugarcane growing states, the percentage of cane used for gur & khandseri during 2001-02 was highest in UP (39.4%) followed by AP (34.5%) Tamil Nadu (31%) and Karnataka (24.4%). With growth of incomes and urbanization, the per capita consumption of gur and khandseri is likely to come down.

4.4.2.8.2 Uttar Pradesh has a very large number of khandseri units. During 1994-95, the khandseri units in UP crushed over 90% of the sugarcane crushed by the khandseri units in four major khandseri producing States i.e., UP, Haryana, Andhra Pradesh and Karnataka. Khandseri has an important share in the sugarcane economy of UP as around 13% to 15% sugarcane is crushed by these units. In UP only around 50% of the sugarcane is crushed by sugar mills. In certain parts of UP, only about 20% cane goes to the sugar mills against an average of nearly 80% in Maharashtra.

4.4.2.8.3 However, most of the khandseri units are small sized with crushing capacity of less than 100 TCD [about 74%]. Nearly 31% of the units operate at less than 50 TCD capacities. About 80% of the units operate with less than 6 rollers, which would mean that these units are likely to extract only about 70% of the juice. Over 1 lakh people are employed in the khandseri units. The overall recovery rate of khandseri units is around
7% to 7.5%. The gur/jaggery is mostly manufactured in the unorganized cottage industry sector. Again, UP has the largest number of gur manufacturing units. Average employment in the gur making units is 10 persons.

4.4.2.8.4 Excepting in times of scarcity, the price paid by khandseri/gur units for sugarcane is lower than the SMP. However, these units invariably make prompt payment for the sugarcane supplied to them, which attracts some of the sugarcane farmers. The growers needing immediate/quick cash for their produce do tend to divert part of their crop to these units though the price paid to them is lower than the SMP. Incidentally, a substantial number of these units [more than 50%] are located within 20 km of sugar factories in UP, Karnataka and Tamil Nadu, which would mean that these units interfere with the cane supplies in the registered areas of the factories. This is particularly so in UP where there is no long-term reservation of area and the linkage of growers with factories is also not direct.

4.4.2.8.5 A connected issue is that in the years of high price for gur, the manufactures are willing to pay a higher price for cane which leads to diversion of cane from the sugar factories, thus adversely affecting their working. As nearly the gur/khandseri units use 26- 27% of the sugarcane, there is also a need to relook at the tax incidence on these units. It may be appropriate to treat khandseri units with above 500 TCD capacity and those with less than 500 TCD capacities differently for excise purposes. The larger khandseri units [above 500 TCD] may also he required to pay SMP for the cane supplied to them atleast during the normal crushing season.

4.4.2.8.6 There is need for improvement in operational efficiency of both khandseri and gur units. One way could be to create a Khandseri Development Fund at the State level through levy of a cess, which could be used for providing need-based support (margin money, low rate of interest) for modernization/expansion to units located outside the reserve area of the factories.

4.4.2.8.7 There is a need for extension work regarding improved methods of gur production and storage not only among the gur producing units but also among the farmers who produce and store gur for their domestic consumption.
Distance between Sugar Mills
4.4.2.8.8 While the sugar industry was delicensed in September 1998, the distance criterion of 15 km has been retained. The minimum distance criterion is necessary to avoid shortage of cane for the factories on a regular basis. The distance of 15 km appears to be adequate for a factory with 2500 TCD plant. However if the plant is bigger say, 5000 TCD or more, the above distance may be grossly inadequate and harm the interests of both the factories and the growers.

4.4.2.8.9 The Committee on Revitalization of Sugar Industry [Shri Tuteja Committee-2004] also looked at this issue and concluded that to ensure availability of sufficient cane for a sugar factory of 5000 TCD, a minimum radial distance of 25 km will have to be maintained. As 5000 TCD is sustainable, the minimum distance between two factories may be increased from the present 15 km to 25 km. The Committee also felt that additional capacity beyond 5000 TCD should accrue through increase productivity and not by expansion of area under sugarcane.

Box – 2
Phased Decontrol of Sugar

|Government has been following a policy of partial control and dual pricing of sugar under the Essential Commodities Act, 1955 which covers sugar and sugarcane. Under this policy the Government as levy sugar collects a certain percentage of sugar produced by the factories. The levy sugar is distributed under Public Distribution System [PDS] at lower prices. The non-levy sugar is allowed to be sold according to the quantity released by the Government as per the free sale sugar release mechanism. The percentage of levy sugar has been reduced over time and w.e.f. 1st March 2002, the levy obligation is now only 10%. The monthly release mechanism was introduced before the independence and has been useful. Sugar is produced only during 4-5 months and released in a controlled manner over the year. The objective is to ensure a reasonable price to the consumers as also to the sugar factories.

The announcement of complete decontrol of sugar from April 2003 resulted in panic sales, which reduced the prices, and many sugar factories suffered financial set back. On request from the industry the Government decided to defer the proposal of decontrol of sugar by two years i.e., upto September 2005.

The Government have also permitted forward trading in sugar.

Margins in Sugarcane Cultivation
4.4.2.8.10 Among the major crops in India, sugarcane is the most profitable crop. Dr. Abhihit Sen, in the ‘State of the Indian Farmer: A millennium study’ on Cost of cultivation and Farm Income worked out the $A_2$ Cost per hectare [all paid out expenses plus rent paid on leased land] and output, at current value for major crops for 5 years time slice of 1981-86, 1988-93 and 1995-2000. He stated, “Sugarcane is the most profitable crop in the country with weighted average profit over paid out costs per hectare at Rs.
30,825 during 1995-2000. Profit per hectare from this crop was highest at Rs. 52,704 in Tamil Nadu followed by Karnataka and Haryana at Rs. 44,283 and Rs. 37,955 respectively. It was somewhat above average but lower in the range of Rs. 23,000–26,000 in major cane producing states of Maharashtra and UP. However, even at this level and taking into account the larger crop period, sugarcane was more profitable than other crop rotations in these states.”

4.4.2.8.11 Even when the margin of the gross value of output over the C2 costs \( [A2+\text{interest on value of owned capital assets including owned land minus land revenue} + \text{imputed value of family labour}] \) are taken for 1995-2000, the sugarcane crop gave larger surplus \( [\text{Rs. 16,705 per hectare}] \) on all India basis than the other crops like wheat \( [\text{Rs. 5242 per hectare}] \), Tur daal \( [\text{Rs. 5458 per hectare}] \), Jute \( [\text{Rs. 3049 per hectare}] \), Cotton \( [\text{Rs. 4221 per hectare}] \) and Rapeseed \( [\text{Rs. 4129 per hectare}] \). The surplus in case of Paddy was only Rs. 2793 per hectare.

4.4.2.8.12 However, with increasing costs of inputs and declining yields during the last 5 years, the margins in sugarcane cultivation have been squeezed in spite of the increase in SMP. In this connection the Commission for Agricultural Costs and Prices in their report for crops sown during 2004-05 season observed as under:

“The primary concern before the Commission is that the cost of production of sugarcane is rising consistently over the years. There is limited possibility to arrest the rising cost of cultivation. At the same time, increasing price for sugarcane affects the financial viability of the sugar mills. A balance has to be struck between the rising cost of production and declining sugar prices nationally and internationally. **The rising cost can be partially compensated through increasing the productivity.** There is, therefore, an urgent need to increase the productivity of sugarcane so that the sugarcane cultivation becomes more remunerative. Presently, there is a wide gap in productivity of sugarcane between tropical and sub-tropical regions of the country, the productivity of sub-tropical region being much less than the national average. The southern states, over a period of time, have increased the productivity through appropriate adoption of new varieties replacing the traditional ones. Such initiative is critically lacking in sub-tropical regions. The Commission emphasizes that the Government
must do all that is needed to enhance the productivity of sugarcane in sub-tropical States. For adoption of new varieties and new technology in sugarcane production, agriculture extension plays a key role which is lacking in many States. The sugarcane mills in southern India, where productivity has gone up substantially over the years, have taken a lead role in extension programme. Going by the success story, the Commission recommends that the “Government should initiate appropriate measures to encourage the public private partnership in research and extension programme with particular emphasis on ratoon management, propagation of disease and pest resistance varieties, integrated plant nutrient management and judicious water management assigning the lead role and responsibility to the sugar mills, for raising the productivity levels of sugarcane. The Government must also pay particular attention to raising yields in the sub-tropical regions”.

The Committee on Revitalization of the Sugar Industry [Shri Tuteja committee-2004] also recommended that suitable steps by various stakeholders [including State Governments] are necessary to ensure that sufficient sugarcane is developed and grown in the mill areas for economic viability of sugar factories.

### 4.4.2.9.0 Strategies to Improve Productivity and Quality of Sugarcane Production

4.4.2.9.1 The strategies to improve the productivity and quality of sugarcane production are discussed in the following paragraphs.

**Seasonal and Varietal Planning**

4.4.2.9.2 Implementation of season wise and variety wise planting programme in the area of each sugar factory is one of the most important aspects of ensuring supply of quality cane throughout the crushing season. The harvesting planning has to be done on the basis of the planting programme in the entire area. There are few factories, which take up scientific season and harvest planning [maturity wise]. The factories, which adopt such planning, get good results. An equally important aspect is increasing the area under better varieties. In Maharashtra the area under COC 671 and CO 86032 varieties is around 80%, which has helped in improving the recovery percentage. Much work in this regard may have to be done in UP, Bihar and MP through extension efforts Shri Tuteja Committee
[2004] referred to earlier, also felt that there was an urgent need for replacement of low sugared variety of cane through extension services in UP.

Production of Quality Seeds

4.4.2.9.3 Good seeds provide the basis for production of good crop in general but it is more so in the case of a crop like sugarcane, which is propagated vegetatively. The sugar factories have an important role in this regard as they could raise nurseries with foundation seeds obtained from the research stations. The factories could also have contract with some progressive farmers for maintenance of nurseries. There is also a need to reduce the seed quantity at the farm level to cut down the costs of seeds. The costs could be reduced substantially by transplanting polybag-raised seedlings or planting one eye-bud setts. Use of tissue culture for breeder seeds to raise foundation seeds is becoming popular in Maharashtra, Tamil Nadu etc. The advantages of tissue culture seedlings raised setts are:

(a) Assured genetic purity and uniformity
(b) High planting ratio
(c) High germination [about 95%]
(d) Early germination
(e) Disease & pest freeness
(f) Quicker coverage of area by improved varieties
(g) Increase in yield of crop

Efforts should be raise say, about 50% of the foundation seed plots annually with tissue culture seedlings in next 4-5 years. The sugar factories may have to be supported for having tissue culture laboratories.

Water Management

4.4.2.9.4 Sugarcane being a long duration crop, water management is important particularly in the tropical region where 15-16 irrigations are required. Drip and sprinkler irrigation have enhanced water use efficiency as compared to furrow irrigation without adversely affecting the soil fertility. However, the high capital cost and irregular electricity supplies are the major constraints in adoption of this system. The after sale service of the equipment also needs improvement. According to studies, drip system
saves irrigation water by about 35 to 55%, fertilizers by about 30% and increases the yield by about 25-30%.

**Soil Fertility and Plant Nutrient Management**

4.4.2.9.5 Sugarcane is an exhausting crop and it is important to take special care to maintain soil health. Integrated nutrient management ensures sustainable production. Use farm yard manures [F.Y.M.], vermi-compost, bio-compost or green manures alongwith needed dosages of NPK and other micronutrients is necessary to maintain sustained high yields. Greater attention needs to be paid for encouraging use of pressmud, sugarcane trash and distillery effluents for improving the sugarcane productivity. Use of bio-fertilizers could helps in reducing the use of nitrogenous fertilizers.

**Crop Rotation and Intercropping**

4.4.2.9.6 It is essential to follow proper crop rotation according to the agro-climatic conditions to improve the biophysical properties of the soil and reduction in pest incidence. Monoculture of cane has resulted in substantial reduction in productivity. Proper sequence of cropping such as sugarcane leguminous crops is suitable for sustainable productivity. Some suggested crop rotations are:

- Rice – Sugarcane – Ratoon – Groundnut
- Groundnut - Sugarcane- Ratoon - Groundnut
- Cotton – Sugarcane – Ratoon – Vegetables
- Vegetables – Sugarcane – Ratoon - Green gram
- Green Manure Crop – Sugarcane – Ratoon – Groundnut

High value inter crops like vegetables, oil seeds, pulses are remunerative and are appropriate for growing as inter crops to provide additional income and reduce risks in the long duration crop of sugarcane.

**Use of Farm Implements and Machinery**

4.4.2.9.7 Tractor drawn sugarcane planter, trash shredder, interculture implements, stubble shaver, rotavator, sub soiler plough etc. are useful and cost effective in sugarcane cultivation. There is need to make these implements available at cheaper rates/hiring at farmer’s level. Use of sugarcane planter and interculture equipment could reduce the labour cost substantially. Cane planting done by planter improves bud germination. On a
rough basis, the cost of planting cane could be reduced by about Rs. 1500/- per hectare with the use of planter. Efforts are needed to design indigenous sugarcane harvesters, which could reduce harvesting cost and also avoid losses due to labour shortages during the peak cane harvesting periods in sugarcane producing States.

Plant Protection - Integrated Pest and Disease Management
4.4.2.9.8 Plant protection is often a neglected part of sugarcane cultivation. To control seed borne diseases like smut, grassy shoot etc. and the pests like scale, mealy bugs etc. the planting material should be treated with fungicides and insecticides. There are parasites for control of bores and predators for controlling sugarcane woolly aphid. The sugar factories/extension agencies could play an important role in adoption of integrated pest control practices collectively by the farmers in an area.

Sugarbeet as a Supplementary Crop
4.4.2.9.9 With the availability of tropicalised sugar beet varieties, there are possibilities of lengthening the crushing season of the factories. It is possible to cultivate sugar beet in the winter season, which is ready for harvest in about 5.5 to 6 months. The preliminary trials have indicated a crop of about 50 M.T./ha with sugar contents in the beet at above 16% is quite feasible. However, it would require additional machinery/other investments in the sugar factories for beetroot washing, slicing, diffusion and clarification of the juice etc. It is rather early to assess the prospects of sugar beet cultivation in sugarcane producing areas. It would be necessary to have after pilot projects to assess the potential of sugar beet and evaluate it as a supplementary feed stock for sugar factories.

Transfer of Technology
4.4.2.9.10 The available technologies are needed to be transferred to the farm quickly and efficiently. Conduct of result demonstrations, operational research projects, problem based training programmes, visits of farmers to the research stations/Agriculture Universities/pilot farms/leading farmer’s fields, publications of literature in local language, exhibitions, use of audio visual aid etc. are essential for transfer of technology. It is also useful to encourage the leading farmers by awards and felicitations etc.
Identification of Appropriate Technologies
4.4.2.9.11 It is customary to say that the small/marginal farmers do not adopt better technologies due to ignorance and unwillingness to change. This may be partly true but often the technology is not adopted due to its inappropriateness to the farmer’s needs, resources and risks taking ability. Efforts are necessary to fit research to the farmer’s needs and requirements. Gaps in support system i.e., extension machinery, credit and input supplies could be the major reason for gap in technology adoption.

Role of the Sugar Factories
4.4.2.9.12 The sugar factories have an important role in sugarcane development in their area. A public private partnership i.e., a close relationship between the research institutions/extension machinery and the sugar factory is essential for cane development in the reserved area. Unfortunately, barring a few, the sugar factories in sub-tropical region have not paid adequate attention to cane development. The factories need to have adequate qualified, trained and motivated Cane Development Staff for the development work. It may be a good idea for each factory to have a cane Development Council representing the farmers, the factory and the Government [including research organizations] to advise in the matters of cane development.
Sugar Development Fund [SDF]

Sugar Development Fund was formed in 1982 under the Sugar Development Fund Act, 1982 passed by the Parliament, for financing various programmes in mission mode for development of sugar industry. A sugar cess @ Rs. 14 per qtl on levy and non-levy sugar in collected and is credited to SDF after deducting the cost of collection of the cess. Eligible purposes of loans from the SDF include modernization of the sugar factories, development of sugarcane in the area of the sugar factory, establishment of Bagasse-based cogeneration power projects, production of Ethanol and defraying expenditure for the purpose of building Buffer Stock with a view to stabilizing prices of sugar etc. The position of the Fund as on 31.03.04 was as under:

<table>
<thead>
<tr>
<th>Description</th>
<th>Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cess collection transferred to the Fund</td>
<td>Rs. 3006.00 crore</td>
</tr>
<tr>
<td>Amount disbursed</td>
<td>Rs. 2528.93 crore</td>
</tr>
</tbody>
</table>

The disbursements under modernization/rehabilitations were highest at Rs.1252.39 crore followed by expenditure on buffer stock maintenance [Rs. 473.84 crore]. The repayments by 31.03.2004 had aggregated Rs. 839.19 crores.

The interest rate on SDF loan, which was 9% p.a., has been recently reduced to 2% below the Bank Rate.

There have been two main problems in availment of loans by the factories from the SDF. The first is the matter of security. The borrowing unit is required to provide either the State Government Guarantee or Bank Guarantee for the loans. This is difficult due to reluctance of the State Government/the cost of Bank Guarantee. The Government may consider alternative security like the charge on sugar factories assets for granting loans under SDF. The second problem is that the unit costs for various investments are not being updated regularly. It is understood no revision has taken place for over 10 years making assistance under SDF grossly inadequate. These cost norms need to be revised periodically. The operations of SDF need to be more flexible and user friendly.

4.4.2.10.0 Import and Export of Sugar

4.4.2.10.1 India has exported about 4 million tons of sugar during the last three years. The value of exports during 2001-02 and 2002-03 was Rs. 1728 crore and Rs. 1693 crore respectively. During 2003-04 [upto July 2004] the exports had already aggregated Rs. 707 crore.

4.4.2.10.2 Sugar was brought under the decanalized system in January 1997 but the quantitative ceilings were fixed. These quantitative ceilings were also removed w.e.f. April 2001. In order to boost exports, the Government have taken following measures:

(a) Sugar meant for exports exempted from levy obligations.
(b) Sugar released for exports treated as advance free sale sugar to be adjusted within 18 months.
(c) Sugar factories allowed reimbursement of expenditure incurred an internal transportation and freight charge upto Rs. 1000 per ton.
(d) Allowed neutralization of ocean freight disadvantage on exports shipments @ Rs. 350 per ton.
(e) Handling and marketing charges upto Rs. 500 per ton on export shipment.

**Box - 4**

**Competitiveness of Indian Sugar**

The Global market in sugar is not truly competitive. The market is highly distorted in the major developed countries like USA, Japan, EU with quotas, tariffs and use export subsidies. This not only affects the export demand for India sugar but also poses a challenge of cheaper imports to the domestic production.

Indian sugar is reasonably import-competitive. Even if Indian sugar is not import-competitive for some units during specific years, there is no reason to be guided by narrow commercial interests of cheaper imports. The spectrum of by-products from sugarcane is competitive and makes it possible to cross-subsidise the farmer without sacrificing the interests of the consumers. It is also necessary to remember that even if the import prices are low, it is quite likely that India’s entry for imports would push up the prices. Further, the competitiveness of other countries in exports may be also in some cases due to their subsidising the exports in different ways.

It is important that the competitiveness of sugar industry is assessed on the use of the entire bio-mass of sugarcane and all the by-products and not only the sugar. However, it is necessary to make all efforts to reduce the costs of sugarcane, labour, transport, packaging etc., to improve the competitiveness of the sugar industry. A strategy could be to develop pragmatic pricing policies of inputs through mutual consultations with the stakeholders of these inputs. This could be quite important in respect of the prices of sugarcane, which constitute about 60% of the cost of sugar.

4.4.2.10.3 Since, sugar shows considerable variations in production, it is appropriate that India builds up its export market. We should also continue our efforts aggressively at international level to get rid of global distortions in the world sugar market. It would also be necessary to increase investment in improving sugar quality to meet international standards. An important connected issue would be to have a pragmatic sugar packaging policy. Compulsory packaging in Jute bags of 100 kg causes two fold problems: it adds to the costs and repacking in 50 kg [internationally demanded pack size] costs additional money.

4.4.2.10.4 Import or sugar was allowed under open General License in March 1994. Customs duty on import of sugar gradually increased to 60% in February 2000 along with countervailing duty of Rs. 850 per ton. During 2002-03 and 2003-04 [upto July only negligible quantity of sugar was imported]. However, in the year of shortfall in production, more imports would be needed. It would be appropriate that when necessary, we may import only raw sugar, which could be processed into white sugar by the industry in India.
4.4.2.11.0 The By-Products

4.4.2.11.1 Sugarcane is a versatile crop. Nearly every part of this bio-mass has industrial potential and uses. The process of making sugar also releases certain by-products having considerable value. So much so that production of some of these products could be profitable enough that sugar could in a way be considered as one of the by-products. In specific situations, the sugarcane could be crushed for making those products and sugar production could be controlled.

4.4.2.11.2 Bagasse, molasses and filter cakes could be considered as the major by-products of the sugar industry and the green tops, cane trash, spent wash, furnace ash and flue gas could be considered as the minor by-products.

4.4.2.11.3 Bagasse is being used as fuel to meet the steam requirements of the sugar factories. A small percentage of bagasse is also used for making paper/particle boards etc. Co-generation of power could be an important by-product of the sugar factories. Technological changes [change from low pressure boilers] could considerably enhance the capability of the industry to generate substantially more power, which could be sold to the National Grid. One problem with this power is its seasonality. However, it is possible to preserve bagasse and use the same for power generation over a larger period. According to the report of the Committee on Revitalization of Sugar Industry [Tuteja Committee Report-2004] the sugar industry has a potential of producing 5000 MW of power.

4.4.2.11.4 Molasses is an important by-product of the sugar industry, which is used extensively for manufacture of potable alcohol, and a number of alcohol based chemicals. An extremely important aspect is that molasses generated ‘Ethanol’ [dehydrated alcohol] is a good oxygenate and could be used as a blend with petrol for motor fuel. Brazil is the world’s largest producer of ‘Ethanol’. There are well over 20 million vehicles in Brazil, which are either pure alcohol powered or run with ethanol mixed petrol [about 22% ethanol blended with petrol]. With increasing prices of crude oil, the promotion of alternate motor fuel has become extremely important.

4.4.2.11.5 The Tuteja Committee [2004] has recommended the following policy interventions:
(a) Oxygenation of gasoline may be made compulsory.
(b) Central Government may formulate long-term policy for blending of ethanol with petrol.
(c) Fiscal and other incentives may be in place for a minimum period of five years.
(d) Purchase price for ethanol may be fixed for a period of 3 years [with suitable price escalation clauses].
(e) The Central Government may take steps to prevent frequent changes in the Power Purchase Agreements by the State Electricity Boards for cogeneration projects.
(f) National Energy Policy may have provisions for (a) mandating the proportion of ‘green’ power to be purchased in the overall power purchase in the State (b) preferential tariff for cogenerated power. The Central Electricity Act may also be suitably amended to provide teeth to the policy to support ‘green’ power.

4.4.2.11.6 A carefully worked out policy in regard to the by-products of the sugar industry could make substantial difference to the sugar industry. The increased profitability, better production planning for sugar and other products [change in product mix] could benefit the growers, help in stabilizing sugar prices, save in foreign exchange [use of ethanol] by reducing oil import bill and help the sugar industry.

4.4.2.11.7 (vi) Another aspect worth considering is the need to develop value added products from sugarcane to boost the demand for cane and improve the profitability of sugarcane cultivators. Some of these products could be tetra-packed cane juice, flavoured jaggery, and syrup from cane juice, liquid sugar and commercial production of vinegar. Perhaps, it may also be possible to produce cane juice wine on commercial scale.

4.4.2.12.0 Sugar Industry - Problems
4.4.2.12.1 It is a well-known fact that the welfare of the sugarcane farmers is closely linked to the working of the sugar factory, which processes the cane grown by him/her. Many sugar mills have also been the focal point for economic and social development in rural areas by generating employment, increasing incomes and creating facilities like schools, colleges, hospitals etc. About 60% of sugar mills in India are in the cooperative sector, 35% in the private sector and the remaining in the public sector. The cooperative form of organization is definitely beneficial in an agro-based industry like sugar. The
cooperative being a member’s organization is concerned with the integrated development of the area, which in the long-term also has beneficial productivity consequences.

4.4.2.12.2 The sugar industry is going through a serious financial crises period. The adverse weather conditions in certain parts of the sugarcane growing-area, attack of pests [white woolly aphid], depressed sugar prices nationally and internationally led to low cash realizations, huge cane payment arrears and serious financial crunch for the industry. In many cases, the value of stock was not enough to cover the working capital loans outstanding to the banks, affecting normal business operations and difficulties in servicing the debts. In some cases, the routine off-season maintenance was affected. The sugar production during 2003-04 was projected at a level of 13.8 million MT against 20.1 million MT in 2002-03. The 2004-05 [Oct-Sept] started with high stocks, low sugar prices and huge cane payment arrears. While, late in the year prices started improving, due to low cane production, it was not possible for well over 100 factories to start crushing during the 2004-05 season creating further difficulties in meeting fixed costs and wage bills etc.

4.4.2.12.3 The Government of India set up a Committee under the Chairmanship of Shri S.K. Tuteja, Secretary, Ministry of Food, Consumer Affairs & Public Distribution, Government of India in March 2004 [referred to earlier in this chapter]. The Committee was to identify the problems faced by the sugar industry and suggest a package for its revitalization to make it viable, self sustaining and globally competitive. The Committee gave its report in December 2004. Some of the important recommendations of the committee are given at appendix-II. The Government may take an early view regarding various recommendations concerning revitalization of Sugar Industry. A weak Sugar Industry would adversely affect the welfare of millions of sugarcane farmers and India would eventually loose its position of premier producer of sugarcane and sugar

4.4.2.12.4 In view of the detailed coverage of the problems of the sugar industry and recommendation for its improvement/revitalization given by the Tuteja Committee, this aspect is not being discussed in this chapter. However, the causes leading to sickness in sugar industry are discussed very briefly in the next paragraph.
4.4.2.12.5 One of the main reasons for sickness of sugar industry is the inadequate availability of the sugarcane which could be due to various reasons including faulty location, inadequate attention to development work, competition from Gur, and Khandseri units, non-availability of adequate and timely inputs to the growers, poor crop and harvest planning and lack of long-term relationship with the growers and the mismatch due to the faster growth in sugarcane crushing capacity as compared to the increase in sugarcane production. Another reason could be the payment to the growers at rates which are not sustainable for the factory. This could be due to fixation of high SAP or payment of excess price due to apprehension of poaching etc. Another reason is the low equity and high indebtedness particularly in the case of the cooperative sugar mills. High interest rates charged by banks, particularly the cooperative banks could be another reason for high debt service obligations. There are also cases where the sugar factories have expanded or diversified without bringing adequate owner’s equity [cooperative sugar factories]. In the years of higher production, the factories have to carry larger stocks increasing the debt burden and interest liabilities. As a matter of fact, sugar industry has to carry stocks for larger periods and any slackening of demand adds to the problems. Obsolescence of technology and machinery is another factor along with unsustainable low installed capacity of the mills or other problems. It may also be stated that in some cases the rigorous Government Controls, which were exercised on the sugar factories in the past, might have also contributed to sickness of some unit.

4.4.2.13.0 Technology Mission on Sugarcane [TMS]

4.4.2.13.1 The importance of the sugarcane cultivation and sugar production in the country cannot be over emphasized. There is a need for improving the productivity, profitability and sustainability of sugarcane farming and also modernization of the sugar industry. The strategies to improve the productivity and quality of sugarcane production have been discussed at an earlier paragraph [15]. The need is to introduce packages of technology, services and public policy for the purpose. At present, there is some multiplicity of the Government departments/organizations, both at the Centre and State, dealing with this subject. Although sugarcane is an important commercial crop providing employment on a large-scale in rural areas, there is no special programme or Centrally sponsored scheme of the Agriculture Ministry exclusively for improving the production
and productivity of sugarcane in the country. The Department of Sugar is implementing the SDF Scheme, which has components for improving the productivity of sugarcane, but perhaps the main focus is with regard to the health of the sugar industry. In the field of research also, though the ICAR is doing its own research efforts through its various schemes and Institutes, the full potential of their research is yet to be achieved.

4.4.2.13.2 Therefore, in order to have a coordinated and focused attention for implementing the strategies discussed earlier to improve the productivity and quality of sugarcane production it is proposed that a Technology Mission on Sugarcane [TMS] be formed jointly with the sugarcane growers’ organisations, cooperatives, sugar factories, banks and research organisations, on the basis of a seed to sugar approach. The objective of the Mission would be to increase the all India average productivity to at least 80 MT/ha. [present average of (2002-03) 64.6 MT/ha against the average yield in many countries already well above 100 MT/ha] and improve the sugar recovery to 11% [from the present 10.3 against the Australia average at 14.25%] with a view to minimizing the cost of production to improve the competitiveness of sugar production with focus on use of better quality seeds, efficient soil, water and nutrient management and taking care of soil and plant health. The above improvements in yield and recovery would help in increasing the production to 25 million tons of sugar in 5 years which would take care of the projected consumption in India at 24.3 million tons.

4.4.2.13.3 The Technical Mission on Sugarcane [TMS] could have three major components:

(a) Intensification of sugarcane research

(b) Technology Transfer

(c) Improving the productivity and quality of sugarcane.

The Intensification of sugarcane research in the following main areas is called for:

(a) Breeding sugarcane varieties/hybrids resistant to biotic stresses including development of transgenic varieties etc. suitable for different agroclimatic and soil conditions.

(b) Improving seed production technology including tissue culture techniques and its standardisation.
(c) Optimisation of resource use efficiency through development of integrated soil, water, nutrition, pest and weed management. Strategies for sustainable productivity and production. Improvement in ratooning for better yields.
(d) Further development work in eco-friendly technologies in IPM, biofertilizers etc.
(e) Development of appropriate and cost effective equipments, tools and machinery for sugarcane cultivation particularly in planting, harvesting etc.
(f) Exploring/evaluating/developing sugarbeet as a supplementary feed stock.

4.4.2.13.4 The above intensification of research would require investment in infrastructure mainly for establishment of a hybridization center for development of sugar hybrids. At present, the major work in this regard is being done at Coimbatore on parents whose flowering synchronizes during a short span at Coimbatore. To supplement the above, another hybridization center could be established. The unused/excess physical facilities already available at existing research stations CENTRES and their suitability may be looked at carefully before a new place is identified for the proposed centre. This facility would be useful to the sugarcane breeders to get additional crossed seeds. Further, the existing facilities for molecular biology and genetic engineering at the research set up at the Sugarcane Breeding Institute, Coimbatore, Indian Institute of Sugar Research [IISR], Lucknow and Vasantdada Sugar Institute [VSI], Pune need to be strengthened for developing varieties including transgenic which are resistant to biotic and abiotic stresses and would give higher yields and recovery. The estimated costs for building these facilities would be around Rs. 20 crores. These developments would help in long-term improvement of sugarcane varieties etc to ensure that the productivity and quality level are sustained and improved.

4.4.2.13.5 Research studies for optimization of resource use efficiency, crop protection, use of bio-pesticides, bio-fertilizers, development of appropriate and cost effective instruments/machinery for sugarcane will have to be supported. A research programme for about five years with clear monitorable output indicators, yearly milestones with final output target will have to be worked out, funded, closely monitored and achieved. A preliminary identification of suggested research studies by the Vasantdada Sugar Institute, Pune are listed at Appendix-I. These could be considered along with similar other suggestions for firming up the research agenda on the subject.
While exact research items, their allocation to different research bodies including Universities, monitoring systems and costs will have to be worked out, on a rough basis an amount of about Rs. 100 crore to Rs. 125 crore may be required for this purpose. The ICAR/Sugarcane Breeding Institute, Coimbatore/IISR Lucknow and VSI, Pune may have to play a major role under this programme. It will also be important that the end users i.e., the farmers and the sugar factories are actively associated in firming up the research programmes etc.

**Technology Transfer**

There is a wide gap between the potential and realized productivity. [Please see the details at para 4 (ii)]. The productivity gap between, the tropical and sub-tropical zone is large. Further, in Tamil Nadu average productivity of 106.8 MT/ha was achieved in 2002-03. Karnataka has also been achieving average productivity of over 80 MT/ha. There are also wide gap in sugar recovery between different States, ranging from over 11.6% in Maharashtra to only 9% in Bihar. The low recoveries could be attributed to poor quality of cane and inefficient making of sugar. As regards the quality of cane, there is much room are improvement particularly in the sub-tropical areas [The average sugar recovery in 2001-02 in sub-tropical zone was about 9.67% as compared to about 10.75% in the tropical zone. Nearly 55% of the factories in Maharashtra, 26% in Karnataka and 11% in each in Andhra Pradesh and Gujarat are having more than 11% recovery of sugar]. However, this would require considerable step-up in extension efforts. The need is to develop and introduce a more effective technology transfer system, which demands proper strategies for effective planning, implementation and evaluation of activities in the technology transfer process. It is said that perhaps the farmers adopt about one third of the available technologies, which needs to be improved.

The objective of the programme under the TMS could be as under:

(a) Develop seed production chain by organizing breeder, foundation and certified seed production programme and available better seeds to the farmers.

(b) Promote use of quality planting material produced by tissue culture.
(c) Transfer production technologies developed by ICAR/Agriculture Universities etc. to farmers through field demonstrations, farmer/extension workers training programmes, farmer to farmer learning and exchange visits to different areas/States.

(d) Bringing more area under efficient irrigation systems like drip, sprinklers etc.

(e) Minimize crop loss by adopting IPM technique, promoting bio-agent production in farmer’s fields.

(f) HRD for updating knowledge/skills of the farmers and field staff.

(g) Reduce cost of cultivation and restore soil health through green manuring, trash manuring and use of press mud, vermi-compost etc. Deteriorating soil health is one of the main reasons for productivity decline/stagnation and it needs more attention.

4.4.2.13.9 The technology transfer programme would have to be done jointly by the staff of the Agriculture Department [AD] and the staff of the sugar factories. The staff of the AD and the factory could prepare farmer wise production programme for each factory in consultation with the farmers and undertake the same after due approval etc. This would become the basis for improving productivity and quality of sugarcane. The farmer training programmes may be given special focus. Assuming about 10,000 to 15,000 farmers in the area of each sugar factory, it may take about 4-5 years to cover all [50 to 60 programmes of about 50 farmers each in a year]. Farmer to farmer learning and visits to other areas/States may be given adequate importance in the training programmes.

4.4.2.13.10 Devising appropriate training programmes keeping in view the farmer’s needs, beliefs, attitudes and problems would be the crucial part of the entire programme of technology transfer. All technologies are not appropriate for all resource conditions. Small and marginal farmers who are resource poor and require technologies, which are appropriate for them, cultivate nearly 45% of the sugarcane area. There has to be integration of the technology support systems, technology generation and technology transfer.

4.4.2.13.11 Much of the anticipated increase in productivity and quality of production may come about through use of quality seeds. Development of seed production chain will be accorded a high priority. This may have to be primarily implemented through ICAR/Agriculture Universities/VSI, Pune etc. Assistance may have to be provided to the
above organizations to maintain genetically pure nucleus seed, production of breeder seeds and foundation seeds. The Sugar factories could also associate in production of breeder seeds depending upon their capabilities and set up. **The programme of production of certified seeds will have to be done by the sugar factories/farmers.** The programme of seed production may be planned in the ratio of 1:10:100 for breeder, foundation and certified units and with a view to replace \( \frac{1}{4} \)th of the area with fresh seed material every year [replacement of seed alone can increase the productivity by about 10 to 12\%].

4.4.2.13.12 Subsidy may be provided for production of foundation/breeder seeds for 5 years. The programme details may have to be worked out by the ICAR in consultation with the State Governments, Agriculture Universities, VSI etc. On a rough basis of subsidy of Rs. 40,000 per hectare for breeder seeds and Rs. 10,000 per hectare for foundation seed, the subsidy component would come to about Rs 16 crore in the first year. The total requirement of subsidy breeder/foundation seed programme for five years would work out to about Rs.100 crore including the subsidy for maintenance of nucleus seeds. Another about Rs. 500 crore may be needed [details will require to be worked out] for training, demonstration and other extension related expenses as additionality to the extension efforts being presently done. This may be worked out on sharing basis between the Center, State Government and Sugar Factories. Out of this additional investment of Rs. 500 crore in extension efforts over five years the Centre’s share may be Rs. 250 crore. Focus of these programmes may be mainly on small and marginal farmers, which constitute about 43\% of the total sugarcane farmers.
Box –5

Sugarcane – DSCL way of bringing prosperity to the farmers

The DCM Shriram Consolidated Ltd (DSCL) started its first crushing season in 1997-98 in U.P. having 16,748 hectare under sugarcane in its area with intensity of sugarcane cropping at only 26%. The challenge to the company was low productivity due to poor technologies, low yielding and susceptible varieties, poor soil conditions and low water availability. The DSCL realized that to ensure regular and adequate supply of sugarcane either the area had to be increased or the yield had to go up and maximum possible share of the sugarcane produced in the area had to come for crushing at the factory. The Company moved in the matter by extending credits for farm inputs, ensuring availability of quality inputs at reasonable rates, providing extension services for popularizing modern agri-techniques, soil testing, providing better varieties of seeds, recommending proper crop rotation, inter-cropping and developing close relationship with the farmers.

The result is that the average productivity has increased in the last four years from 42 ton/ha to 55 ton/ha and the yield in paired row spacing upto 75 ton/ha to 120 ton/ha. The farmers are also getting additional income of Rs.5000 to 10,000 per hectare from inter-cropping. Further the intensity of sugarcane cultivation has improved to 52% and the area under sugarcane to 50,000 hectare.

The Company established the first Haryali Kisaan Bazar (HKB) in July 2002 and now there is a chain of 16 HKBs in four States viz. Uttar Pradesh, Haryana, Punjab and Rajasthan. These units provide fertilizers, insecticides, pesticides and seeds of different crops, agricultural implements, diesel, petrol and lubricants through BPCL petrol pumps to ensure better quality and quantity cooking gas to farmers through Bharat gas agency, different FMCG products of daily use, veterinary medicines, green card facility by using ATM through rural branch of ICICI Bank and giving crop extension services.

Improving the Productivity and Quality of Sugarcane Production

4.4.2.13.13 It is felt that the sugarcane cultivation could be revolutionized by a strong proactive role of the sugar factories, banks, financial institutions and the Government both the Centre and the State Governments. The broad objectives of the programme could be stated as under:

(a) To increase the productivity and quality of sugarcane in all sugarcane growing States, of the country while keeping the area under sugarcane constant.

(b) To maintain sustainability of the sugarcane farms.

(c) To increase the profitability of the sugarcane farmers.
(d) To encourage the sugar factories to establish additional facilities for sugarbeet processing.

4.4.2.13.14 This is the most important part of the project. The benefits of focused research support, extension work, improved availability of better quality seeds/varieties and inputs has to be converted into higher productivity and better quality of output. The farmers wise production programme worked out for each factory would be the basis. There could be two main components of this programme. The first relating to establishment of certain infrastructural facilities like Soil Testing Laboratories and Tissue Culture Laboratories at the factory level to support the programme for scientific cultivation and improve the availability of superior planting material in their reserved area. To provide incentive to the sugar factories to invest in creating the above facilities, the Government may provide 25% capital subsidy for development of about 250 Soil Testing Labs [unit cost of about Rs. 40 lakh] and 125 Tissue Culture Laboratories [unit cost of nearly Rs. 105 lakh]. The amount may work out to about Rs. 50 to 60 crore. The factories may raise the balance of 75% from their internal resources/banks etc. The soil testing labs should work to prepare a soil health card for each farm and specially assess the micro nutrient deficiencies so that the same could be applied on the soils to improve their productivity. It is felt that this development alone could improve the productivity of farms by at least 15-20%. Further, it may also be necessary to encourage establishment of bio-fertilizer units. The use of nitrogen fixing and phosphate solubilizing biofertilizers in sugarcane significantly increases the cane yield besides as much as 25% saving in inorganic nitrogen. The potential demand for all types of biofertilizers for sugarcane is estimated at 0.90 lakh MT against the production of 0.13 lakh MT. It is, therefore, suggested that the Government may encourage establishment of such units [about 300 units] by providing 25% subsidy. On a rough basis the subsidy may work out to nearly Rs. 45 - 50 crore.

The second component of the programme i.e., taking up scientific cultivation, using proper nutrients based on soil test reports, introduction of drip irrigation, need based farm mechanization, improving ratoon management, green manuring, improving irrigational facilities, using better quality certified seeds, providing adequate credit for purchase of inputs etc. could be supported by banks under their normal development programmes.
However, it would mean intensification of efforts, development of new model schemes, training of the field staff of the banks, close monitoring and eventual evaluation. The National Bank for Agriculture and Rural Development [NABARD] which has an important promotional and developmental role may be nominated as the nodal agency to prepare factory wise credit intensification programme based on farm plans [referred to earlier] prepared by the extension staff and the factories, to be incorporated in the District Potential Linked Credit Plans prepared on an annual basis by NABARD for all the districts in the country. These programmes may have to be dovetailed with the District Credit Plans of the banks. These plans may be aggregated at the State/National level. It is felt that sugarcane cultivation presents excellent opportunities for the banks to intensity their credit operations. Sugarcane is a highly profitable crop and has assured marketing tie up with the sugar factories. The need is to have a focus and an agency for coordinating, problem sorting and giving a lead to the entire investment programme. A kind of role, which is tailor, made for NABARD.

4.4.2.13.15 NABARD may also lead the training of the bank staff in this credit intensification programme. The Banker Institute of Rural Development [an autonomous national level training establishment established by NABARD] may take the lead role in preparation of course contents, reading material and training of the trainers of the banks and other training institutions involved in training of the bank staff.

4.4.2.13.16 The Government may provide a small service charge to NABARD for the credit intensification programme at say 0.5% on the basis of incremental credit disbursed under the programme. Assuming incremental lending of Rs. 10,000-12,000 crore, a provision of Rs. 60 crore would be adequate.

4.4.2.13.17 A High Level Committee of about 15 members consisting of the representative of Government of India, Four State government [on rotation], NABARD, RBI, Commercial Banks [on rotation], the Federations of the Cooperative Banks, ICAR and Industry may be constituted under the Chairmanship of the Union Agriculture Minister or his nominee Government of India with Chairman/ MD, NABARD as Member Secretary. The Committee may broadly oversee the entire programme.
4.4.2.13.18 Similar Committees may also be created at the State level under the Chairmanship of Agriculture Production Commission of the State and the Incharge of the Regional Office of NABARD as the Member Secretary to oversee the programme in the State. For undivided and focused attention the TMS may be placed under the exclusive change of a senior level officer in the Govt. of India to the designated as ‘Mission Director’. Similarly, in the major sugarcane growing States, the Governments may also designate a State level ‘Mission Director’ to act as the ‘nodal officer’ for the programme.

4.4.2.13.19 To sum up the total cost of the programme may be around Rs. 900 crore in a five year time slice as detailed below:

A. Intensification of research efforts : Rs. 125 crore to Rs. 150 crore
B. Technology Transfer : About Rs. 600 crore of which the Centre’s share may be Rs. 300 crore
C. Improving the productivity and quality of sugarcane : Rs. 160 crore

Needless to say, the above are rough estimates and the details would require to be worked out.

4.4.2.13.20 The Project would aim to reach in 5 years, all India average productivity of above 80 MT/ha and recovery level of 11% which would produce nearly 250 lakh tons of sugar [on the assumption that about 62.5% cane would be available to the sugar factories for crushing]. This would mean additional sugar production of about 50 lakh tons in the fifth year of the project, from the level of production of 2002-03, which would value [on the basis of Rs. 14000 per ton] about Rs. 7000 crore. For achieving an average productivity of 80 MT/ha it is expected that the average productivity in the tropical region would increase to 95 MT/ha against the level of 82.73 MT/ha in 2001-02 and the average productivity in sub-tropical region would increase to 70 MT/ha against the average of 52 MT/ha in 2001-02. It is also assumed that the area under sugarcane in tropical and sub-tropical region would continue to be in the ratio of 60:40 as at present.

* During the last 4 years the total use of sugarcane for khandsari gur, chewing seed and other purposes has never exceeded 135 million MT. In view of the possibilities that the demand for these purposes may not grow [may decline] the cane available for sugar would be 225 million ton i.e. about 62.5% of the production. This is based on an estimated total sugarcane production of 360 million MT [450 lakh hectare with average production of 80 MT/ha] and average sugar recovery of 11%.
4.4.2.14.0 SUMMARY OF RECOMMENDATIONS

4.4.2.14.1.0 SUGARCANE PRODUCTION

4.4.2.14.1.1 Good seeds provide the basis for good crop in general but it is more so in the case of sugarcane crop, which is propagated vegetatively. The programme for production of breeder seeds/foundation seeds needs to be supported. The sugar factories could play an important role in raising nurseries with foundation seeds from research stations. Replacement of seed is important. The replacement of seeds by the farmers in fourth year could improve the yield by 10% to 12%.

4.4.2.14.1.2 There is an urgent need for replacement of low sugared variety of cane in UP, Bihar, MP etc. through extension efforts.

4.4.2.14.1.3 There is a need to reduce the seed quantity at the farm level. The cost of seeds could be reduced substantially by transplanting polybag-raised seedlings or planting one eye-bud setts.

4.4.2.14.1.4 Tissue culture needs to be encouraged for assured genetic purity, better and early germination, quicker coverage by better varieties and higher sugarcane yield. The sugar factories need to be supported for having tissue culture laboratories.

4.4.2.14.1.5 Proper care of ‘ratoon’ crop could increase the sugarcane yield. Maintaining required plant population through gap filling by settlings, use of adequate fertilizers, need based micro - nutrients and plant protection care could help in increasing the yield of ratoon crop. Training of the farmers and more intensive extension work by the extension staff and sugar factories is called for.

4.4.2.14.1.6 There is a need for the sugar factories to have soil testing laboratories so that soil health card for each plot of land in the reserved area could be prepared and need based micronutrients and fertilizers could be applied. This alone could improve the yields by 15% to 20%.

4.4.2.14.1.7 The cane area reservation needs to be on a long-term basis (5 to 10) years with provision for review by the State Government, to ensure better sugarcane development efforts by the factories and effective linkages with the growers. Social audit
of the arrangement may be taken up which could also facilitate the decision-making in case of dispute.  

4.4.2.14.1.8 Monoculture of sugarcane has resulted in substantial reduction in productivity. Proper sequence of cropping such as sugarcane-leguminous crops is suitable for sustainable productivity.

4.4.2.14.1.9 The high capital cost and irregular electricity supplies are the major constraints in adoption of drip/sprinkler irrigation systems. The after sale service of the equipment also needs improvement. According to studies, drip system saves irrigation water by about 35 to 55%, fertilizers by about 30% and increases the yield by about 25-30%.

4.4.2.14.1.10 Crop specific equipments need to be popularized. The sugarcane planting done by planter improves bud germination. On a rough basis, the cost of planting could be reduced by about Rs. 1500/- per hectare with the use of planter. Efforts are also needed to design indigenous sugarcane harvesters, which could reduce harvesting cost and also avoid losses due to labour shortages during the peak cane harvesting periods in sugarcane producing States.

4.4.2.14.1.11 The sugar factories/extension agencies could play an important role in adoption of integrated pest control practices collectively by the farmers in an area.

4.4.2.14.1.12 Greater attention needs to be paid in use of crop residue from sugarcane and products much as press mud, sugarcane trash and distillery effluents for improving sugarcane production.

4.4.2.14.1.13 There is scope for increasing the use of bio-fertilizers in sugarcane cultivation. The use of nitrogen fixing and phosphate solubilizing bio-fertilizers in sugarcane significantly increases the cane yield besides as much as 25% saving in inorganic nitrogen. The Government may support establishment of bio-fertilizers units by providing capital subsidy.
4.4.2.14.2.0 CANE PRICE
4.4.2.14.2.1 SMP needs to be announced by the Government at least one year in advance to give price signals and also to help in the allocation of land/other resources. If the SMP could be announced for a longer period say about 3 years, it would help in better planning and stabilizing cane production. There should be very strict enforcement of the law regarding timely payment of sugarcane price to the growers.

[Para 4.4.2.7.7 & 4.4.2.7.12]

4.4.2.14.2.2 The SMP needs to carefully balance the interests of the growers and the factories. While the sugar prices were declining/stagnating, the SMP for sugarcane continued to increase which also contributed towards increasing the sugarcane price payment arrears.

[Para 4.4.2.7.7]

4.4.2.14.2.3 Though suggestions have been made, it may not be appropriate to have SMP on regional basis.

[Para 4.4.2.7.7]

4.4.2.14.2.4 Linking the sugarcane price to the sucrose contents of the cane as is done in some other countries could encourage the farmers to grow better varieties. However, it could be done only after the equipments for assessing sucrose contents of the cane are tested and become generally acceptable by the growers. This needs to be done on a priority basis. However, for the present it may be possible to fix incentive prices for varieties, which have higher sucrose contents with a view to encourage the farmers to take up cultivation of these varieties.

[Para 4.4.2.7.9]

4.4.2.14.2.5 Prima facie the Bhargava formula for sharing the surplus of income from the sale of sugar over the cost of production 50:50 by the growers and the factories appears to be in order save for the implementation delays. If it could be decided quickly at the end of the season, the impact would be much better.

[Para 4.4.2.7.11]

4.4.2.14.3.0 CANE PROCUREMENT [SUPPLY] ARRANGEMENTS
4.4.2.14.3.1 In U.P. and Bihar the system of sugarcane procurement for crushing on the basis of ‘Parchies’ issued to the farmers through the Cooperative Cane Societies/Union needs to be reviewed. This system leads to delay in reaching the sugarcane to the factories [collection is usually at the purchase centers] and is also not farmer friendly.
This system is also not effective in developing linkages between the farmers and the factories. [Para 4.4.2.7.17]

4.4.2.14.3.2 Though the State Governments impose penalty for poaching of sugarcane, unless it is adequate it does not serve as a deterrent to the factories. In Punjab, for example, the penalty on conviction in a court was only Rs. 2000/-, which was grossly inadequate. This needs review by the State Governments. [Para 4.4.2.7.3]

4.4.2.14.3.3 It may be appropriate to treat Khandseri units with above 500 TCD capacity at par with sugar factories for payment of SMP during normal cane season and also for excise duty etc. [Para 4.4.2.8.5]

4.4.2.14.3.4 The electronic weighing scales needs to be installed at all purchase centers/factory gates, so that the sugarcane growers are satisfied about the accuracy of weight and it would reduce their waiting time. [Para 4.4.2.7.18]

4.4.2.14.3.5 As 5000 TCD is sustainable; the minimum distance between two factories may be increased from the present 15 km to 25 km. [Para 4.4.2.8.9]

4.4.2.14.4.0. KHANDSERI/GUR PRODUCTION

4.4.2.14.4.1 There is need for improvement in operational efficiency of both khandseri and gur units. One way could be to create a Khandseri Development Fund at the State level through levy of a cess, which could be used for providing need based support [margin money, low rate of interest] for modernization/expansion to units located outside the reserve area of the factories. [Para 4.4.2.8.6]

4.4.2.14.4.2 There is a need for extension work regarding improved methods of gur production and storage not only among the gur producing units but also among the farmers who produce and store gur for their domestic consumption. [Para 4.4.2.8.7]

4.4.2.14.5.0 SUGAR DEVELOPMENT FUND

4.4.2.14.5.1 The Government may consider alternative security like the charge on sugar factories assets for granting loans under SDF. The unit costs for various investments under SDF assistance are not being updated regularly. It is understood no revision in unit cost has taken place for over 10 years, with the result assistance under the SDF is grossly
inadequate. These cost norms need to be revised periodically. The operations of SDF need to be more flexible and user friendly. [Box – 3]

4.4.2.14.6.0 SUGAR BEET
4.4.2.14.6.1 The potential of the sugar beet crop [which could be cultivated in winter] needs to be analyzed and considered carefully as supplementary feed stock particularly with a view to increasing the crushing period and saving on water use. It would be necessary to take up pilot projects in different areas to evaluate sugar beet as a supplementary crop. [Para 4.4.2.9.9]

4.4.2.14.7.0 SUGAR- EXPORT/IMPORT
4.4.2.14.7.1 Since, sugar shows considerable variations in production, it is appropriate that India builds up its export market. We should also continue our efforts aggressively at international level to get rid of global distortions in the world sugar market. It would also be necessary to increase investment in improving sugar quality to meet international standards. An important connected issue would be to have a pragmatic sugar packaging policy. Compulsory packaging in Jute bags of 100 kg adds to the costs and repacking in 50 kg bags [internationally demanded pack size] costs additional money. [Para 4.4.2.10.3]

4.4.2.14.7.2 In the year of shortfall in production, imports would be needed. It would be appropriate that when necessary, we may import only raw sugar, which could be processed into white sugar by the industry in India. [Para 4.4.2.10.4]

4.4.2.14.7.3 The competitiveness of sugar needs to be assessed on the use of the entire biomass of sugarcane and all the by-products and not only sugar. [Box - 3]

4.4.2.14.8.0 VALUE ADDED PRODUCTS
4.4.2.14.8.1 There is a need to develop value added products from sugarcane to boost the demand for cane and improve the profitability of sugarcane cultivators. Some of these products could be tetra-packed cane juice, flavoured jaggery, and syrup from cane juice, liquid sugar and commercial production of vinegar. Perhaps, it may also be possible to produce cane juice wine on commercial scale. [Para 4.4.2.11.7]
4.4.2.14.9.0 RESEARCH
4.4.2.14.9.1 Efforts are necessary to fit research to the farmer’s needs and requirements. Gaps in support system i.e., extension machinery, credit and input supplies are some of the contributory factors in large gap in technology adoption. [Para 4.4.2.9.11]

4.4.2.14.9.2 Public private partnership between the research institutions/extension machinery and the sugar factories is essential for cane development in the reserved area. This could facilitate extension work and needs to be encouraged. [Para 4.4.2.9.12]

4.4.2.14.10.0 ETHANOL/COGENERATION
4.4.2.14.10.1 Tuteja Committee [2004] recommendations regarding policy interventions in the matter of ‘bio-fuel’ and co-generation of power by sugar factories need favourable consideration.

- Central Government may formulate long-term policy for blending of ethanol with petrol.
- Fiscal and other incentives for ethanol production may be in place for a minimum period of five years.
- Purchase price for ethanol may be fixed for a period of 3 years [with suitable price escalation clauses].
- The Central Government may take steps to prevent frequent changes in the Power Purchase Agreements by the State Electricity Boards cogeneration projects being implemented by sugar factories.

National Energy Policy may have provisions for (a) mandating the proportion of ‘green’ power to be purchased in the overall power purchase in the State (b) preferential tariff for co-generated power. The Central Electricity Act may also be suitably amended to provide teeth to the policy to support ‘green’ power. [Para 4.4.2.11.4]

4.4.2.14.11.0 SUGAR INDUSTRY
4.4.2.14.11.1 The recommendations of the Tuteja Committee [2004] regarding revitalization of the sugar industry needs an early decision. [Para 4.4.2.12.3]
4.4.2.14.12.0 TECHNOLOGY MISSION ON SUGARCANE [TMS]

4.4.2.14.12.1 The average all India yield of sugarcane has been declining during the last five years. Even earlier it had shown tendency of stagnation. During the last 12 years ending 2002-03, the highest average yield of 71.3 MT/ha was achieved as far back as in 1994-95. On the basis of projections, the demand of sugar is likely to reach 24.3 million tons against the production of 20.1 million tons in 2002-03. In view of the limitations in increasing area under sugarcane, the Central Government may establish a Technology Mission on sugarcane with the objective of improving the productivity and quality of sugarcane production. The Technology Mission should help in achieving the All India average sugarcane yield of at least 80 MT/ha [against 64.6 MT/ha in 2002-03] and an average recovery of not less than 11% [against 10.36% achieved in 2002-03] in five year

[Paras 4.4.2.3.2 & 4.4.2.13.2]

4.4.2.14.12.2 The TMS may have three components i.e., intensification of sugarcane research, technology transfer and improving the productivity and quality of sugarcane production. The research establishments may work on breeding sugarcane varieties for different agro-climatic/soil conditions and higher sucrose contents, making available foundation seeds to factories/select farmers for improving availability of quality seeds, suggest improved practices, develop appropriate tools and provide the research support for sustaining increase in productivity and quality of sugarcane. The Agriculture Department & the Sugar Factories would have to work together and provide extension support. The sugar factories need to prepare soil health cards for each plot of land in the reserved area growing sugarcane and also the farm wise production programme.

[Paras 4.4.2.13.3 & 4.4.2.13.6]

4.4.2.14.12.3 Each sugar factory may constitute Cane Development Council representing the farmers, the factory and the Government [including research organization] to advise the factory on the matter of sugarcane development.

[Para 4.4.2.9.3]

4.4.2.14.12.4 NABARD may be declared the nodal agency to coordinate the availability of credit and prepare a factory wise credit plan based on the farm wise production plans prepared by the Sugar Factories/representative of the extension Department of the State Government.

[Para 4.4.2.13.14]
4.4.2.14.12.5 A Committee at the National level chaired by the Hon’ble Union Agriculture Minister and having representation of the concerned Ministries of the Central Government, State Government [on rotational basis] Banks, [on rotational basis] ICAR, Industry, RBI and NABARD may oversee the programme. Appropriate Committees at State level may also be constituted to averse the implementation of the programme in the respective State. [Paras 4.4.2.13.17 & 4.4.2.13.19]

4.4.2.14.12.6 For undivided and focused attention, the TMS may be placed under the exclusive charge of a senior level officer in the Government of India to the designated at Mission Director. Similarly the major sugarcane growing states may also designate a State Level Mission Director to act as the modal officer for the programme. [Para 4.4.2.13.18]

ACKNOWLEDGEMENT

The National Commission on Farmers acknowledges the cooperation extended by the Vasantdada Sugar Institute, Pune and the Indian Institute of Sugar Research, Luknow which helped in holding consultations with the officers of the Government of India, State Governments, Industry, Banks, Research Organisations, Experts and Farmers on the subject at Pune and Luknow respectively. The sharing of knowledge and experiences by the participants in the above meetings and also during the consultations held at New Delhi is acknowledged.

Appendix II
Major Recommendation for Sugar Industry by Shri Tuteja Committee

1. To ensure that the sugar factories in drought / flood affected States get adequate working capital to start their crushing operation in 2004-2005, a package of assistance for rescheduling their debts may be provided. Under this package sugar factories, which were operational in 2002-03 sugar season, may be covered.

2. All loans as on 31-03-2004 may be deferred / rescheduled to long term loans repayable in 10 to 12 years, beside a moratorium of both interest and principal for 3 years stating from 2004-05. Loans to be covered under this package are the deficit in stock value as on 31-03-03 (Rs. 1,500 crores), which was rescheduled into working capital term loan, deficit in stock value as on 30-09-04 (Rs. 1,000 crores) and other term loans (Rs. 4,000 crores). The exact terms of the package may be worked out by NABARD and RBI (in consultation with the state governments) on a case-to-case basis taking into consideration the debt service obligations and the capacity to repay of these sugar factories.

3. NABARD may provide (allow) pre-seasonal loans as per their existing norms to sugar factories in Maharashtra and Karnataka.

4. Government of drought/ flood affected states may be allowed additional open market borrowings to help sugar factories to meet the fixed costs and 75 % entitled wages (of 2004-05 and 2005-06 season and arrears of 2003-04 season) of mills which were operational in 2002-03 sugar season but may have to remain closed in 2004-05 and 2005-06 sugar seasons due to no-availability of sugarcane; The State government may offer this as loan to sugar factories at a rate of interest of 4 % per annum, the Central Govt. may provide interest subsidy to meet the difference between the coupon rate on the bonds raised through additional market borrowings and 4% as was done last year when State Governments were allowed the same facility for clearing cane price arrears.

5. A scheme similar to the one available for integrated textile units should be sanctioned for the sugar sector for reducing their debt service burden.

6. In the case of units set up keeping the incentives of 1993 and 1997 in view, the excise duty payable on levy sugar namely Rs. 38/quintal may be charged on 50 % of sugar sold
by these units under their free sale quota as against excise duty of Rs.71/quintal payable on free sale sugar.

7. All eligible cases for restructuring in the sugar industry may be taken under the Central Debt Relief [CDR] scheme. The present minimum principal exposure of Rs. 20 crores may be brought down to Rs. 10Crores.

8. Working capital to cooperative sugar factories may be made available through National Cooperative Development Corporation (NCDC) at a subsidized rate of interest. For this purpose, NCDC may arrange cheaper funds through External Commercial Borrowings (ECBs) and the Government of India may accord permission as well as provide guarantee in this regard.

9. A body like BIFR may be set up for rehabilitation of cooperative sugar mills and NCDC may be appointed as the Nodal agency for preparing rehabilitation packages for sick cooperative sugar mills.

10. The financial restructuring of cooperative sugar factories under rehabilitation package may generally comprise the following components:

- Conversion of full/part of outstanding State Government loans into equity.
- Infusion of additional equity by the State Government/members of the society.
- Reschedulement of outstanding loans of banks & financial institutions and waivers concessions in interest on outstanding loans of cooperative sugar mills.

11. NCDC while acting as a nodal agency may work out a suitable rehabilitation package involving the above steps and also, working out required amount of interest subsidy for revival of a sugar factory, in consultation with term lenders, banks and National Federation of Cooperative Sugar Factories.

12. In order to improve profitability of sugar industry through value addition to by product like bagasse and molasses, cooperatives sugar mills having potential for setting up of diversification projects may be encouraged. In this context, NCDC may also explore the possibility of arranging external commercial borrowings and Government of India may accord permission as well as guarantee in this regard.
13. VRS in the sugar sector may funded by commercial banks.

14. Necessary assistance may be provided from SDF for the following purposes:
   - Installation of appropriate effluent treatment systems (to achieve zero discharge) including installation of heat exchangers for cooling and condensing, tertiary treatment of effluents and labs for monitoring effluent quality.
   - Installation of bag filters/high efficiency wet scrubbers/electronic precipitator to meet standards of air emission

15. As sugar industry do not discharge any toxic or highly polluting wastes, it may be placed in ORANGE category.
CHAPTER - 4.5

ENHANCING PRODUCTIVITY, PROFITABILITY, STABILITY AND SUSTAINABILITY

CONSERVATION, CULTIVATION AND MARKETING OF MEDICINAL PLANTS

4.5.0 Introduction: The Challenge and the Potential

4.5.1 Medicinal and aromatic plants provide a window of opportunity to concurrently strengthen health, food, nutrition, and livelihood security of farm families and agro-ecological security of the environment. Their potential is especially immense in the Indian context where traditional systems of medicine have been used over the years to address human, animal and plant health. Globally also, the potential is being recognized and it is becoming increasingly apparent that Health for All can be assured only by strengthening traditional systems of medicine.

4.5.2 Business opportunities in recent years are expanding due to diversified usages of herbals in pharma, nutraceutical, cosmetic and agro-chemical industries. Whereas India’s current turnover from the herbal industry is estimated to be around 50,000 million rupees (40,000 million rupees in the domestic market, 10,000 million rupees in exports) given the burgeoning global demand trends, this size can increase exponentially in the next 10-15 years. According to a World Bank study, the world market is poised to grow to US $ 5 trillion by 2050. That being the scenario, India as one of the biodiversity rich countries with a rich heritage of traditional medicine has the potential to be a leading player in the sector. This calls for major sprucing up first on the domestic front in the areas of cultivation, research, standardization and regulation to ensure safety, quality and efficacy, and pricing and marketing. A focused strategy has to be undertaken simultaneously to place our products in the international market.

4.5.3 The key challenges in this endeavor are doing research to establish the safety, quality and efficacy of the traditional health products and gearing up supplies via large-scale cultivation and appropriate post-harvest technologies. This again calls for immediate research into development of sources for quality planting materials and
standardization of agro-technologies and agro-economics. But if done in a proper manner, the medicinal plants sector can be a major area for generation of employment and income.

4.5.4.0 Background

4.5.4.1 India has one of the world’s richest medicinal plant heritages. It has 10 biogeographic zones and 25 biotic provinces. About 8000 species of plants are used in local health practices for human, veterinary and agriculture related applications. Around 1800 species are systemically documented in the codified Indian Systems of Medicine - Ayurveda, Unani, Siddha, and Gso-rig-pa which source their drugs from medicinal plants. Over 10,000 herbal drug formulations have been recorded in codified medical texts of Ayurveda. Thus, we are uniquely positioned to capture the new opportunities both locally and globally in providing increasingly sought-after holistic healthcare solutions for human, veterinary and agricultural purposes.

4.5.4.2 Of the indigenous systems of medicine, Ayurveda, the traditional system is based on Vedic scriptures and is practiced all over India. Siddha is extensively practiced in Tamil Nadu and adjacent States. Unani, also known as Greek / Arabic systems, is popular among the Muslims, particularly in the Deccan plateau. Gso-rig-pa or the Tibetan system of medicine is practiced in the trans-Himalayas and NE. More than 15 lakhs practitioners of both the codified and folk streams of the Indian Systems of Medicine and Homeopathy (ISM&H) use medicinal plants in preventive/promotive and curative applications. Already there are 4.6 lakh, registered practitioners of ISM&H and around 7843 registered pharmacies of Indian Systems of Medicine (ISM) and 857 of homeopathy. The World Health Organization (WHO) has estimated that about 80% of the population of developing countries relies on traditional medicines, mostly plant drugs for their primary healthcare needs. Moreover, about 25% drugs in modern medicine are also derived from plants. On account of the fact that crude derivatives of medicinal and aromatic plants are non-narcotic having little or no side effects, the demand for these plants is on the increase in both developing and developed countries. Examples of plants with effective derivatives are Aswagandha (*Withania somnifera*) widely used as an immuno-modulator; Sarpagandha (*Rauvolfia serpentina*) for reducing blood pressure; Sallai Guggal
(Boswellia serrata) for rheumatoid arthritis; Chitrak (Plumbago zehlancia) for improving digestion and Turmeric (Cucuma longa) for diabetics. There are estimated to be over 25,000 effective plant-based formulations available from indigenous medicine for a wide variety of health conditions, including for animal and plant health.

4.5.4.3 Several hundred genera are used in herbal remedies and in traditional or folklore medicines throughout the world. They are used in the form of crude drugs which are dried parts of the medicinal plants, roots, stem, wood, bark, leaves, flowers, fruit seeds and in some cases whole plants and their extracts. There is a much smaller number of plants used by allopathy from which individual active constituents are isolated and used as medicines, either alone or in combination. The structure of isolated molecules can also be used as precursors for synthesis the drugs.

4.5.5.0 Current Scenario

4.5.5.1 The growing needs of the pharmaceutical industry in the country have created problems of supply. One of the major difficulties being experienced by the industry is that of obtaining sufficient quantities of medicinal plants for the manufacture of genuine medicine.

4.5.5.2 In India, 90 percent of the collection is still from the wild. Only few medicinal plants are cultivated on a large scale. The information regarding the area under cultivation and States where cultivation is in progress is given in the table below:
### Table: Area under cultivation of major medicinal plants in India

**Source:** EXIM Bank Occasional Paper No.98 “Export Potential of Indian Medicinal Plants and Products” published by Quest Publications in 2003

4.5.5.3 It was only during the Eighth five year plan period, that a programme for the development of medicinal plants was launched by the Department of Agriculture and Co-operation (DAC) with a focus to conserve the medicinal plants by the establishment of herbal gardens, production of planting material by the establishment of nursery at different locations, demonstration of the cultivation practices through the establishment of demonstration plots, provide the support for expansion of area and infusion of technologies through effective transfer. But farmers often face disappointment in absence of effective marketing system. The Department of Indian System of Medicines and Homeopathy (now AYUSH), also initiated the programme during the Eighth five-year plan to develop agro-technology of some selected medicinal plants. Some laboratories of CSIR have also contributed in identification of molecules of medicinal
plants. While there is an expansion in area under medicinal plants certain transit and other regulations of the forest departments discourage the cultivation of medicinal plants by the farmers. Even plants growing in the farmers’ field require clearance certificate from the District Forest Officer for marketing.

4.5.5.4 The Planning Commission, Government of India had set up a Task Force on Conservation and Sustainable Use of Medicinal Plants in 1999. The Task Force studied the issues involved and submitted an exhaustive report in 2000 (hereinafter referred to as TF Report on MP). Setting up of the National Medicinal Plants Board was an outcome of the recommendations of this group. Most of the recommendations of the group however remain on paper. Their implementation in itself would give proper thrust to the development of the sector.

4.5.5.5 As per a study undertaken by the Foundation for Revitalization of Local Health Traditions (FRLHT), Bangalore at present, about 926 medicinal plant species are involved in All India trade; of these 760 species are largely collected from the wild. About 48 species are exported and 42 are imported. As per an EXIM Bank estimate, the international market of medicinal plants related trade is to the tune of US $ 60 billion per year having a growth rate of 7% per annum. The annual exports of Indian plants are valued at Rs.10,000 million. In terms of market share in production value, India holds only the sixth place with a mere 7 per cent share whereas China accounts for about 33 percent. 70 percent of the medicinal plant exports from the country is in the form of crude drugs and extracts and only 30 % is finished products.

4.5.5.6 The Basic Chemicals, Pharmaceuticals & Cosmetics Exports Promotion Council (CHMEXCIL) is responsible for the promotion of medicinal plant based products and APEDA is entrusted with the task of export promotion of medicinal plants. So far, setting up of agri-export zones for Aromatic and Medicinal Plants in Kerala and Uttaranchal, have been approved by the Government.

4.5.5.7 According to the TF report on MP, we also import some 15 medicinal plants, which can be made domestically available as well (e.g. Akkalkada - *Anacuclus pyrethrum*, Jestimadh - *Glycrrhiza glabra* (Pakistan, Iran, Afganistan), Dalchini - *Cinnamomum zeylanica* (China), Gajpimpli - *Scindapus officinalis*, and Kankol - *Piper cubeba* (Indonesia), Chopchini - *Smilax china*, Maiphal - *Quercus infectoria* and
Revchini - *Garania pictoria* are mostly met through imports). There are also imports of medicinal plants of foreign origin and medicines like ginseng.

4.5.5.8 No authentic recorded information is available about the volumes of trade of medicinal and aromatic plants within the country. The collectors (both permit holders and others) exploit the plants, through tribals, local people and forest dwellers. The collected material is passed on to the traders in towns and cities. Each of the major traders has one or more indigenous drug manufacturers and private pharmacies as their customers for purchasing the raw plant material from their contractors and other growers of medicinal and aromatic plants in different parts of the country. In the absence of any regulatory mechanism, the trade of these plants, particularly medicinal plants is very secretive. Prices for individual medicinal plants vary with demand, availability and quality. The quality characteristics are ill-defined; for some species they depend on the percentage of active ingredients, appearance, absence of foreign matter and other particular conditions that may be laid down in the relevant pharmacopoeia, formulary or in the purchaser’s specific requirement. Moreover, the ingredients for the final product are contained mostly in certain part(s) of the plant e.g. leaves, root stem, flower, and fruit, and not the whole plant. But due to the ignorance of the collector coupled with the need to earn more, the whole plant is destroyed.

4.5.5.9 The traded materials include leaves, barks, fruits, seeds, roots rhizomes, gums, husks etc., the value of which range between Rs.10/- to Rs.145/- per kg. The major industrial buyers of dried raw herbal materials in the domestic market are around 50 companies which include leading companies like Zandu, Baidynath, Sami Labs, Himalaya, Natural Remedies, Dabur, Sandu, Charak, long-standing traditional manufacturers like Arya Vaidyashala, Kottakal, Kerala, Ayurvedic Pharmacy, Gururaja and a large number of small level manufacturers of Ayurvedic medicine and some leading herbal extracts exporters.

4.5.5.10 The WHO has introduced a series guidelines for collection, cultivation, production, certification, registration and marketing of medicinal plants, through five important practices viz., Good Agriculture Practice (GAP), Good Manufacturing Practices (GMP), Good Laboratory Practice (GLP), Good Clinical Practice (GCP), Good Selling Practice (GSP). The Indian medicinal plants-based industry is yet to take to this in
a concerted fashion. Under the ISM&H, most pharmacies are family owned companies and trade is largely unregulated.

4.5.6.0 SWOT Analysis

4.5.6.1 A SWOT analysis can help bring out clearly the areas needing attention. The TF report on Medicinal Plants, 2000, highlighted the following constraints facing the sector, which are still relevant:

i) Depletion of the resource-base, which is the foundation of the entire sector.

ii) Decline of folk traditional medicines, a source of primary health care for an estimated 800 million people in the country.

iii) Impoverishment of rural people, who are stewards of the resource base and the holders of traditional ecological and medical knowledge, through inequitable marketing channels.

iv) Medicinal plant trade is inefficient, imperfect, informal and opportunistic.

v) Crude drugs supply situation is shaky, unsustainable and exploitative; adulteration takes place.

vi) Deficient toxicology studies and standard preparations to improve the quality, efficacy and effectiveness of the traditional drugs.

vii) Unsustainable wild harvesting

viii) Lack of coordination amongst various stakeholders such as Govt. of India (Ministry of Agriculture, Environment & Forests, ISM&H, S&T etc), State Governments, private traditional medicine sector, research institutes, NGOs, international networks etc.

4.5.6.2 Going by the SWOT matrix, a sectoral analysis of the Medicinal Plants sector is attempted below.

4.5.6.3.0 Strengths

4.5.6.3.1 India has vast agro-climatic zones, is biodiversity rich, and has a long history of traditional medicine practice. Given the agro-climatic suitability and variability, biodiversity richness and treasure of traditional knowledge and historical use pattern of Medicinal and Aromatic Plants (MAPs) in India, the prospects for intensifying and diversifying the country’s herbal industry are unmatched.
Traditionally, medicinal plants constitute the principal healthcare resource for the majority of our population. Herbal-based and traditional medicines have also been major components of the animal healthcare system in the country also. India being home to every fourth farmer as well as to every fourth livestock in the world, the importance of the country’s industry in veterinary and livestock disease management can hardly be overemphasized.

**4.5.6.4.0 Weaknesses**

The weaknesses are in the areas of quality standardization, cultivation, market and research.

**4.5.6.4.1 Quality**

i) The greater part of the collection is from the wild. The collected material are sold to traders of medicinal and aromatic plants, who using their limited knowledge sort out the saleable ingredients in a crude manner thus resulting in contamination with other material leading to poor quality standards.

ii) As bulk of the harvest (wild and cultivated) is marketed as raw product several of the active principles and ingredients are lost rather fast; poor post-harvest management, processing and marketing and lack of marketing chains severely affect quality, safety and efficacy of the products.

iii) Many of the plants are sensitive to climatic conditions and require specific temperature, humidity etc., while being stored and / or transported. Hitherto, this aspect remained neglected both by the growers and collectors. Since the international market is highly conscious about the quality aspects of the production, our success in the export market has been insignificant.

**4.5.6.4.2 Cultivation**

i) The major constraints being experienced by the cultivators of medicinal plants are non-availability of quality planting material of improved varieties, lack of development and extension support in the cultivation and processing, and unorganized marketing.

ii) The cost of production is usually high for the cultivated crops as compared to those collected from the wild as a result of which the cultivation of the crops has not been an attractive proposition for the farmers.
4.5.6.4.3 **Marketing**

i) Some of the other key factors hindering cultivation of medicinal plants are lack of, information on market prices and dependable market support, Good Agricultural Practices, proper support from banks and financial institutions, price parity with wild produce, access to good storage facilities and appropriate post harvest technology. No systematic distribution and marketing network exists, and the growers have to depend on the middlemen who generally deprive them of their legitimate share of revenue.

ii) India is today even importing some plants needed by the industry to meet internal demand. 70% of the exports are in the form of crude drugs.

4.5.6.4.4 **Research**

i) Despite the long and historical tradition and high dependence on herbs for health security, the research and technology development efforts in the sector have remained meager.

ii) One of the major difficulties of medicinal plants cultivation on a large scale is the lack of scientific and appropriate agro-technology and agro-economics for different climatic zones of the country. Although several organizations viz., Indian Council of Agricultural Research (ICAR); CSIR Laboratories, various Indian Universities, etc., and Research Councils of indigenous systems of medicine, Department of Indian System of Medicine (ISM – Ayush), Government of India, have taken up the work of development of appropriate agro-techniques, and development of high yielding varieties of medicinal plants, more effort and multi-centric on-farm trials are needed keeping in view the demands of trade and industry.

4.5.6.4.5 **Opportunities**

i) The revival and renewal of global interest in traditional medicine offers a great opportunity for growth of the sector. World demand for herbal products has been growing steadily at 10-15% per annum.

ii) There are great opportunities for strengthening and synergizing the herbal-based human and livestock healthcare systems in the country. Therefore, the need for the amalgamation of currently scattered ethno pharmacological information through a
systematic validation of efficacy, doses, administration and safety component coupled
with availability issue of the traditional herbs can no longer be ignored or delayed.

iii) It is extremely relevant to not only conserve the rich herbal biodiversity but also to
cultivate it for utilization by the industries to meet the domestic and export demands in a
sustainable manner and also to maintain desired quality standards. Sustainable production
and continuous value addition will ensure effective conservation of the target populations
and species. Shift from collection and conservation mode to conservation and cultivation
for utilization will ensure purity, authenticity and availability of MAPs for pharma and
aroma industries including poly-herbals for nutraceuticals.

iv) We can set a national target to turn into a major exporter of finished products instead
of raw drugs, to emerge as a global competitor in this sector.

v) Cultivation has to be initiated for import substitution of the produce being imported
currently.

vi) The national system, encompassing the public, private, industry, practitioners of
traditional healthcare systems, NGOs, CSOs, tribals and other communities and farmers,
can be organized and strengthened to judiciously harness the resources towards
interactively enhanced and sustained health, nutritional, income and employment
security. The National and State Medicinal Plant Boards can play a pivotal role in
bringing together the various stakeholders.

4.5.6.4.6 Threats

i) Infrastructure in the Indian systems of medicine is below optimal in all areas -
education, R&D, standardization and quality control. There is growing pressure for
communicable benchmarking of products and processes.

ii) At present about 90 per cent collection of medicinal plants is from the wild and since
about 70 per cent of the plant collections involve destructive harvesting, many species are
endangered/ threatened. Some are in the Red Data Book and threatened with extinction.
No measures are taken to replenish the natural resource base through fresh planting. Such
collections constitute poor quality raw materials as these contain veritable adulterants.
This trend must be halted especially in case of those species where the extraction from
the wild has been highly destructive as in the case of Swertia, Picrorrhiza, Podophyllum,
Aconitum, Commiphora, Terminalia, Coscinium, Santalum, Valeriana, Rauvolfia, Jatamansi.

iii) As the price paid to the gatherers tends to be very low they often mine the plants with a view to earn more income. As a result several plant species have become endangered.

iv) China’s business approach to development of the sector has seen it corner a large share of the export market. They have a good regulatory system in place in line with international requirements with regard to GAP, GMP, GLP, GCP and GSP. The work they have done to place ginseng for instance in the world market is commendable. Besides meeting its domestic requirements, China is earning US $ 5 billion from world trade.

v) WTO, patents, biopiracy, IPR issues related to traditional knowledge in the face of lack of organized database of traditional knowledge, threatening resource base and changing regulatory environment of the importing country are major threat factors.

vi) In recent times, there have been reports in the news of reservations abroad about the efficacy of herbal medicines and their being a potential health hazard due to high concentration of heavy metals. The bio-efficacy of ISM has to be urgently established and proper labeling and certification done.

vii) India has to spruce up fast, if it does not wish to be left behind. If critical investments are not made into research India will miss the bus. Critical investments for establishing standards of safety, quality and efficacy are essential, as they will dramatically increase the consumer acceptance of traditional herbals both in India and globally.
4.5.7.0 Recommendations

4.5.7.1 Given the current scenario, the recommendations of the TF report on MP can be reiterated to begin with as strategies for kick starting the sector. Extracts from the recommendations are reproduced below:

The policy for sustainable development of medicinal plants resources should aim at -

a. *In-situ* conservation of medicinal plants in protected areas, herbal gardens, sacred groves, preservation plots and forest areas rich in medicinal plants.

b. *Ex-situ* conservation through cultivation, Joint Forest Management, gene banks etc.

c. **Developing medicinal plant conservation areas (MPCAs) inside as well as outside protected areas.**

d. Research and development efforts for developing agro-techniques, extension & dissemination of information on cultivation of super genotypes.

e. Establishing linkages between farmers and pharmaceutical industries for promotion of organic and contract farming.

f. Formalising and organising marketing by providing information and possible interventions at various levels.

g. As prices paid to the gatherers tend to be very low, they often ‘mine’ the natural resources, as their main objective is to generate an income. Formalisation of market may resolve the problems of exploitation and impoverishment of gatherers.

h. Policies regulating safety and efficacy need to be evolved based on recognition of the uniqueness of tribal and folk medicines, and this should be linked to intellectual property rights to ensure that community benefit from the use made of their technology.

i. A regulatory system is urgently needed to restrain indiscriminate and illegal wild harvests:
   - Setting up of *in-situ* forest gene banks;
   - Critically endangered species should not be harvested.
   - A list of species and habitats from which collection is permissible should be scientifically prepared by every State Forest Department and over harvesting
should not done; there should be switchover to plants which are not in the red list.

- Harvesting should be done at the right stage in scientific and non-destructive manner.
- Good Trade Practices should be followed in the collection – fair price paid to primary collectors and fair cess paid to the State Forest Department.
- Recommended post-harvest procedures should be followed.

4.5.7.2 From the farmers’ perspective, technical advice on package of practices for cultivation, availability of quality seeds, certification and labeling, promotion of contract cultivation, harmonization of collection and cultivation to ensure competitive price are immediate needs for promotion of medicinal plant cultivation as a viable livelihood option. All initiatives should focus on the goal of establishing safety, quality and efficacy standards for medicinal plants products.

4.5.7.3 Some of the steps needed in this direction are: designating competent certification agencies; encouraging cooperative farming of medicinal plants; R&D on the top 10 export priority species with respect to quality, efficacy and safety; addressing emerging issues on patenting and IPR for traditional knowledge.

4.5.7.4 Immediate measures are needed in the areas of Policy, R&D Input supply, Market and Pricing Support as discussed below. A Mission mode approach is warranted. A National Mission on Medicinal and Aromatic Plants maybe organised, to ensure that the sector receives the integrated attention it deserves. The recently approved National Horticulture Mission (NHM) includes MAPs, but given the already large number of fruit, vegetable and flower species to be addressed under the NHM, the MAPs may not receive the special support, attention and leadership it urgently needs. The Mission should converge and synergise policies on agriculture, forestry, environment, health and pharmaceuticals and commerce covering the components impacting the growth and development of MAP industry. Pending the preparation of a full-fledged Mission, a distinct Mini-Mission may be organized for MAPs under the ongoing NHM. A dynamic leader in the area of medicinal plants and herbal medicine may be appointed as the coordinator of the Mini Mission for MAPs.
4.5.8.0 **Policy Action**

4.5.8.1 There is need for Policy support for science-based judicious conservation, utilization and commercialization of medicinal plants to promote health, food, nutrition, employment and income security of the people. In this context, the following policy elements are essential:

i) The National Mini Mission should on priority basis address the issues of R&D (quality, safety and efficacy), *in-situ* conservation, sustainable wild harvest, cultivation, pricing and price parity, marketing, trade, income of the growers, partnerships, institutional supports, networking, availability of quality materials, training, information system and awareness.

ii) **The Mission should have a Policy Guidance Committee (PGC), an apex level body comprising the Ministers of Agriculture, Health, Environment & Forests, Commerce, and Science & Technology, to give direction.** The PGC could guide the restructuring of the National Medicinal Plants Board (NMPB) on the lines of NDDB, to enable it to perform effectively and work for the objectives and targets of the Mission. The functioning of the Board in a competitive and professional manner will in itself help resolve many of the issues facing the sector.

iii) The NMPB’s website should include details of medicinal plants programmes of all Government Departments and Ministries, e.g. DBT, DST, CSIR, ICAR, MoRD, MoEF and AYUSH, in order to avoid duplication of efforts. It should be one-stop window for all information on the sector, sourcing from all the various departments and ministries.

iv) The Mission via NMPB should support

- creation of network of certification agencies using internationally accepted standards for both cultivated and wild produce;
- support forestry sector to set up State level Seed Centres for collection and certification of planting material from forests
- wholesale supply of quality seeds of high priority species;
- initiate mega projects under PPP for high priority tree species.
- emulate DBT models for PPP on R&D projects for herbal products.
v) Promotion of Public-Private Partnerships (PPP): There should be clear cut policies on agro-forestry and reforestation involving tree medicinal plants, tree and non-timber product harvest from forests, land reforms to enable replanting of degraded and wasted lands under PPP mode. The National Mission should through PPP with an ethical private sector company, strive to launch one global herbal product of the outreach like the Chinese *ginseng* every five years, with backward linkages for generation of rural employment.

vi) Promotion of Contract farming: Appropriate codes of conduct should be in place and confidence building among stakeholders

vii) Mandate different Commodity Boards to promote intercropping with plantation crops like coffee, rubber, spices and coconut

viii) The Mission should address the issues of quality and standardization, regulatory controls, code of conduct for collectors/gatherers from the wild in accordance with the CBD and Gene Treaty provisions.

ix) The Mission via NMPB should advocate institutional support through credit not only for production but also seed grants for value addition, market development, promotion of grassroots organizations, SHGs, cooperatives, insurance coverage and price support system for medicinal plants and establishment of community herbal gardens. It should support promotion of ecosystem specific home and *community herbal gardens* to enhance household human and livestock health security.

x) The Mission should encourage NABARD to examine providing Seed Fund to NGOs & CBOs to support viable community-owned enterprise for collection, cultivation, processing of MPs for income-employment benefits to rural poor. NABARD and EXIM Bank should therefore have a package of grant and credit programmes for MPs, and not just crop support programmes

xi) The Mission should support enhanced investment in MAP research, technology development and industry growth to effectively integrate the phyto-industry with national health, nutrition and rural employment.

xii) The TF report on MP had recommended that the Forest Department establish 200 “*Vanaspati Van*” in open forest areas (each having an area of about 5000 hectare) for commercial supply of crude drugs to pharmacies and for exports. The “*Vanaspati Van*”
should be managed by a registered society headed by Divisional Forest Officer under JFM system.

xiii) IPR and TK: Policies regulating safety and efficacy need to be evolved based on recognition of the uniqueness of tribal and folk medicines, and this should be linked to IPR to ensure that community benefit from the use made of their technology. A library database can be prepared and maintained under the National Innovations Foundation (NIF). The library can be used as proof of prior art by the examiners of Patent offices, nationally and internationally.

xiv) Crude drugs of standard quality need to be identified and preserved as the reference standard. The TF Report on MP had therefore recommended establishment of a National Repository of Crude Drugs of ISM&H with an excellent herbarium having authentic reference samples. This center should have the crude drug samples (processed medicinal plants), herbarium specimen, chemical finger print profiles, anatomical slides, supporting literature and a collection of living plants. It should provide easy access to wide range of groups including traders, medical practitioners, plant chemists, TM students, academics, regulators as well as the pharmaceutical industry. User services will also have to be made available. This repository should then become the official certification centre for raw materials. The drug industry can get the raw materials certified from the centre.

xv) To ensure quality, there should be Statutory State Drug Testing Laboratories. It is necessary to designate safety evaluation centres with Good Laboratory Practices (GLP) norms. This will facilitate the acceptance of the drugs at a global level.

4.5.9.0 Research, Technology Development and Extension

4.5.9.1 Research on standardisation of quality, safety and efficacy for the best traditional products is sub-critical. Very little value has been built on the indigenous and traditional knowledge. The All India Coordinated Research Project of ICAR should be revamped and networks forged with other related research institutions – CSIR, CMAP, CDRI, industries, NGOs and CBOs and ICMR, AYUSH, MoRD, DST & DBT. The network will not only partly offset the problems linked with low investment in the sector, but would also open the gates for wider domestic and global acceptance of traditional knowledge products.
4.5.9.2 Recent studies have shown that in addition to the genetic variation of different populations of a given species and from one part to the other part of the same plant, the GxE effect is generally very high. Using new tools and technologies, the R&D system must fill this knowledge gap so that the future developments could be knowledge-based.

4.5.9.3 Research on all aspects of MAPs with special reference to improving their productivity, medicinal qualities, availability of quality planting materials, storages, cold chains, processing, value addition and adaptability to grow under ex situ conditions should be undertaken. Multi-location testing of promising materials, both local and introduced, should precede recommendations for production in identified agro-geographic locations.

4.5.9.4 ICAR Research Institutions and Agriculture Universities should undertake to evaluate germplasm, identify sub species, and develop varieties. TK leads should be harnessed to help identify research priorities.

4.5.9.5 The TF report on MP had recommended the following, which continues to be of importance –

a. Development of agro-technological packages under different ecological conditions and information on intercropping, rotation cropping and use of bio-fertilisers, organic farming etc.

b. Human Resource Development of farmers by organising training and awareness programme on various aspects of medicinal plants sector development including seminars and conferences.

4.5.10.0 Quality Planting Material

4.5.10.1 One of the major constraints faced by the cultivators of medicinal plants is the non-availability of quality planting material. Given that a large part of the collection is currently from the wild, there is need for synergistic inter-sectoral program between the forestry and agricultural sectors wherein germplasm is supplied by the forestry sector and selection, breeding and agro-trials is done by the agricultural sector, for promotion of cultivation.

4.5.10.2 Planting Material Supply Network (PMSN) in the form of Herbal Bio-villages must be set up so that small scale farmers can generate material for large scale farmers.
Plant Tissue culture units of R&D institutes should provide certified nucleus stock to small farmers.

4.5.10.3 Village level Medicinal Plant Nurseries and Seed Production Centres of commercially viable plant species managed by trained women SHGs and agricultural/botany graduates can develop as suppliers of quality planting material. They should have back-up support from the R&D institutions and forward linkage with concerned Institutions and Farmers’ forums. The National Medicinal Plant Board through their State wings can coordinate this programme and buy back and distribute to farmers through appropriate delivery points. Seed Banks may be established for plants that are in demand for commercial use.

4.5.10.4 Tissue Culture for large-scale production of medicinal plant seedlings and introduction of such facilities at village/community level in the areas potential for medicinal plant cultivation managed by trained educated housewives or unemployed botany/agriculture graduates and attached to some reputed local organizations (private/NGO or Govt.) can play an important role.

4.5.10.5 For protection of different endangered medicinal plant species, encouragement should be given to Government and semi-government tissue culture laboratories for multiplication of endangered species so that planting material can be supplied on large scale.

4.5.10.6 Large-scale availability of high quality planting material can be promoted by developing a protocol for bulk production of super genotypes and seedlings through a network of nursery of medicinal plants.

4.5.10.7 Collection and sale of forest tree seeds by the Forest departments is also a source for planting material.

4.5.10.8 State Agricultural Universities maybe assisted to establish quality control laboratories so as to fix quality parameters for various plant species and their varieties.

4.5.11.0 Marketing

4.5.11.1 Assurance of market is the major factor for giving impetus to cultivation. Closely linked is the development of related infrastructure, need for network of godowns for storage and on-site post harvest facilities. Market research should be strengthened and
geared to identify the most appropriate species, real time information on supply and demand and trade balance, pricing and price levels and parity, and diversification prospect.

4.5.11.2 Market Infrastructure:
i) NABARD and/or Ministry for Rural Development should support the establishment of a network of decentralized scientifically designed storage godowns in rural areas – that could store harvested produce. NGOs & CBOs should also be encouraged to manage these godowns. Primary value addition at the collectors and farmers level should also be studied and adequate infrastructure support like quality testing lab, drying yards, raw drug processing unit, packing unit be set up in identified districts.

ii) Post harvest technology for the plants, their grading, packaging and method of storage need to be developed. Small cost effective processing units to serve the need of a cluster of villages will be a good idea. Primary processing at village level will reduce problem of storage and the risk involved.

iii) Being matters of health and nutrition concern, GAP, GMP, HCCAP and other such measures should be routinely adopted in the production–processing–consumption chain. This calls for intensive training and educational efforts to create quality, standards and trade literacy and awareness at all levels and among all stakeholders.

iv) Research organizations must devise rapid methods for analysis of quality attributes of the raw and finished products for pricing, adulteration control and IPR protection. The quality measures should be harmonized with international standards and guidelines especially to capture new opportunities in the globalised economy and to ward off non-tariff barriers to trade.

4.5.11.3 Demand Forecasting:
i) An efficient agency, say a research institute should be identified to establish a long-term MIS that could be supported by MoRD and the NMPB. Through Market intelligence, the industry must define the quantity of plants required for at least 3-4 years so that farmers can be informed accordingly and necessary facilities could be extended to the farmers to realize the production target. Marketing chains should be studied and restructured with a view to increase profitability to growers.
ii) Industry must spell out the quality of produce that would be acceptable to them at a fixed price for a fixed period. R&D organizations should be in a position to generate the desired material if not available and make the input available for cultivation. Appropriate packages of incentives and subsidy for cultivation and product development must be devised on case-to-case basis in area specific mode and on the criteria of marketing.

iii) Detailed studies should be undertaken on plants that have the highest global demand and a systematic approach devised to export them. The TF report on MP had recommended focused strategies to popularise twelve major Indian Plants For Various Ailments in the World Market and listed the plants –

2. Bala (*Sida Cordifolia*) for neurological disorders.
4. Geloy-Gaduchi (*Tinospora cordifolia*) As immuno-modular
5. Chiraita (*Swertia Chirata*) for liver disorder
6. Kutki (*Picrorrhiza kurroa*) for liver disorder
7. Gudmar (*Gymnema sylvestre*) for diabetes
8. Ashoka (*Saraca asoca*) Uterine Tonic
9. Satavari (*Asparagus racemosus*) Anti-Ulcer, Aprodisiacs
10. Amala (Amalaki) (*Emblica officinalis*) for Rasayana, Geriatrics
11. Arjuna (*Terminalia arjuna*) for Cardiac disorders
12. Gugglu (*Commiphora wightii*) for cholesterol related disorders, Arthritis

iii) There is a need to conduct extensive R & D on these plants not only to improve their varieties, enhance availability but also to establish their efficacy in various clinical conditions mentioned above. While undertaking this research there has to be active interface with the industry so that there is proper demand assessment and the research leads to patents being obtained and new drugs being marketed for public benefit and for exports. A well-formulated strategy has to be worked out for placing the product in the world market. Indian Missions abroad should be equipped to play a positive role in dissemination of information on Medicinal Plant-based products.

4.5.11.4 *Contract farming*, a new opportunity elaborated in the new APMC Act, is ideally suited for promoting the cultivation of medicinal plants and crops. Appropriate codes of
conduct on contract farming suited to the needs and aspirations of the various stakeholders, especially the small and marginal farmers, should be formulated and judiciously implemented. The extant success as well as unsuccessful experiences of contract farming in this sector should be critically analysed and necessary institutional and service supports should be provided to rapidly multiply the successful experiences. Promotion of cooperative farming and **Small Medicinal Plant Farmers’ Estates** may also be explored. More Farmers’ groups like *Gram Mooligai, Jeevani, Sanjeevani*, should be organized to take up MP cultivation in a focused manner. Lease of common property land for the purpose may be explored.

4.5.11.5 In order to give the power of economies of scale to small farmers, **Medicinal Plants Growers’ Association** each covering about 100 ha could be formed on the model of SHGs. Capacity building in the areas of cultivation and marketing will have to be organised. Such growers’ association can enter into MoU with companies to outsource raw materials for drugs. Herbal estates could also be promoted for bringing about an end-to-end approach in relation to medicinal plants and herbal medicine. Currently such community-based enterprises constitute even less than 0.01 percent of the medicinal plant production and trade. This should be raised to the tune of at least 5 to 10 percent during the next 4 to 5 years. MoRD should promote direct financing of innovative NGOs & CBOs through its employment programs for this purpose.

**4.5.12.0 Pricing**

4.5.12.1 There is no organized pricing policy for MAP products, raw or processed. There is often a huge disparity in the prices of wild harvests and cultivated harvests, the former being much cheaper. This price disparity is the main deterrent to the domestication and cultivation of medicinal plants. A transparent and adequately researched and scientifically assessed pricing policy and system should be in place in the Forestry and Agricultural sectors to bring price parity for all harvests. Uttaranchal has initiated this approach and its outcome should be closely monitored both by the State and National Medicinal Plant Boards and, if found encouraging, the approach should be adopted/adapted in other States.
4.5.12.2 The above move will help also in minimizing, if not completely eliminating, the unsustainable indiscriminate wild collections, as also in promoting sustained production through organized cultivation. The industry would thus need to be more quality conscious and nature-friendly.

4.5.12.3 The Commission on Agricultural Costs and Prices (CACP) of the Ministry of Agriculture, in close consultation with the Ministry of Environment and Forests, and Department of Ayush of the Ministry of Health, particularly the NMPB, and Ministry of Commerce, should address the problem of pricing. A special Working Group, involving the various stakeholders - the growers, the foresters, the gatherers, the traders, the industry and the practitioners, should be constituted to critically examine issues and to suggest guidelines for price fixation and to declare prices of medicinal plant produce.

4.5.13.0 Agro-ecologically and Socio-economically Differentiated Approach

i) Striking a balance between Conservation – Collection – Cultivation - Production, collection and marketing of Medicinal Plants/Crops have so far generally been on ad-hoc basis. Flash success stories such as those on vanilla and Safed Muesli, (Chlorophytum borivilianum) have enthused several medium to large-scale farmers and corporate houses to diversify towards Medicinal and Aromatic Crops (MACs), often ignoring agro-ecological suitability. This “quick fix” approach, with little understanding and appraisal of medium to long-term marketing and pricing trends, has often been short-lived and shaky. The supplies soon outpaced demand and the resultant price crashes and market failures adversely affected the farmers.

ii) The NMPB has previously identified 32 priority species. These needs to be reprioritized and differentiated, based on a set of criteria and indicators as listed below and State-wise lists prepared:

   (i) domestic and export demand
   (ii) ecological sustainability
   (iii) social acceptability
   (iv) financial viability
   (v) agro-technological feasibility
(vi) availability of quality planting materials
(vii) market chain product storage and distribution, and
(viii) regulatory support.

iii) Using the above criteria and other new and emerging indicators, the prioritization process should be kept in a dynamic mode. Special attention should be given to matching the soil, water, biodiversity and cultural attributes with the sustained and enhanced production of the intended and potential species particularly to facilitate creation of effective export zones to ensure judicious supply-demand management. The State Medicinal Plant Boards should provide packets of ready cultivation procedures and marketing aspects to farmers. The priority lists should be reviewed periodically, say once in three years.

iv) For a smooth and gradual transition from wild harvest to cultivated production of the MAPs, the following aspects must be addressed:

- Threat status of various species should be re-assessed so that time bound cultivation strategies of different groups can be drawn. A tentative classification may have categories like critically endangered perennials, endangered but highly regenerative, vulnerable but collected by destructive means, under threat due to high level of consumption etc.

- Special attention should be paid to endangered, vulnerable and threatened species for their conservation and cultivation, and on case to case basis impose restriction or even ban harvesting of endangered species from their natural habitats

- While part of the requirement may be met by sustainable harvesting from the wild by tribal and forest communities / dwellers, bulk of the requirement should be met through planned and suitably organized cultivation by area-specific local farmers. Further, for species in larger demand, the supply should be entirely based on cultivation

- Areas rich in medicinal plants can be developed into Herbal Sanctuaries, so that this unique biological wealth can be safeguarded and conserved for posterity. The TF report on MP had recommended the establishment of 200 Medicinal Plant Conservation Areas (MPCA) covering all ecosystems, forest
types and sub-types in the country, (inside protected areas viz. national park, wild life sanctuary, biosphere reserves, preservation plots etc.) for in-situ conservation of important species.

- Species not amenable to commercial farming need to be conserved in their natural ecosystem for regulated utilization. A mission mode approach needs to be adopted for developing this area. The rare medicinal plants should be conserved in well-established gardens. Medicinal plant conservation areas need to be identified across the country, in different climatic and agro-ecological regions

- Over-harvested endangered perennial MAP species and tree medicinal plants in high demand should be planted in public-private partnership framework as agro forestry systems on priority basis. Degraded forestlands and wastelands should be planted with such tree species, which will not only provide a sort of “forest” cover but would also become important source of income and employment.

v) State Agricultural Universities, Department of Agriculture and nurseries of the Department of Horticulture should undertake the programme of collection and conservation of different species of medicinal plants prevalent in a region and their multiplication on a large scale. KVKs and NGOs working in the area can assist in the process. Many of the medicinal trees will need 8-10 years for gestation and readiness for economic growth. Farmers need to undertake a cropping system, which will be suitable to give them economic return from the first year onwards. Therefore intercropping with species of shrubs and trees as a package should be developed through State Agricultural Universities.

vi) An end-to-end approach, linking the producer, processor, industry and the consumer, with effective backward-forward linkages, involving the partnership of farmers, research and extension services, credit and input support, processing and market is a success story of a mega project on guggal in the arid zones of Rajasthan. The public-private partnership (PPP) is functioning in a model form with a win-win situation for all partners. Based on supply-demand analysis and agro-ecological compatibility, the guggal experience should be multiplied not only for guggal alone but also for other MACs. In
order to capture scale of economies, small farmers estates (SFE) and MAP self help
groups, especially women SHGs, for the various domains should be created and
supported through formal credit, training and group marketing. Such an approach will
also be helpful in adoption of the quality, safety and efficacy standards.

vii) **Herbal Biovalleys** may be developed on the model of the Silicon Valley for
computer software, for providing the infrastructure needed for the conservation and
sustainable use of medicinal plants. The Herbal Biovalley will provide the biological
software essential for a dynamic medicinal plant industry. The infrastructure for seed
multiplication including tissue culture facilities, establishment of nurseries of elite
material, validation, certification and producer-oriented marketing and other centralised
facilities to facilitate efficient decentralized production, will have to be provided. A
Project Design Team may be immediately constituted with members drawn from the
NMPB, NBDB, NABARD and APEDA, to prepare a Business Plan for the world’s first
Herbal Biovalley in Kerala as recommended by the Kerala Commission on WTO
Concerns in Agriculture, and at other suitable locations in Western and Eastern Ghats and
western, central, eastern Himalayas and in the NE region.

**4.5.14.0 Organic Farming of MAPs**

The demand for organic food and other products has been growing rapidly.
Organically grown MAPs are seen as “doubly green” products and have tremendous
global demand and appeal. Hill States like Uttarakhand have declared themselves as
Organic States and organic pockets are being set aside in other States, where MAP
species, most suited to the settings, constitute the preferred crops. However, the organic
movement is yet to be streamlined in terms of selection and use or detoxification of sites,
standardization and application of production protocols, certification of the process and
the product, pricing and marketing. The various stakeholders, led by NMPB, must
develop a detailed road map and monitoring mechanism for organic MAPs industry
addressing production, certification, pricing and marketing issues.
4.5.15.0 Information Portal on Medicinal and Aromatic Plants

4.5.15.1 Database and information on various aspects of MAPs are highly inadequate. The NBMP was supposed to have established the information portal, but the work is far from satisfactory. The information system must be strengthened and a competent agency (University or research institute) must undertake comprehensive survey to have full real time information on demand and supply and species and domain-wise production, pricing and marketing. Databases on GAP (good agricultural practices) and GMP (good manufacturing practices), indigenous and traditional knowledge of various medicinal, nutraceutical, aromatic, cosmetic and agri-chemical products should be created. The library database on TK on medicinal plants should be linked to the portal.

4.5.15.2 Details of medicinal plant programs of all Government departments and ministries should be given. There should be a national database on the medicinal plants of India with State-wise checklists and reliable information on botanical identities, distribution, threat status and agricultural information.

4.5.15.3 The reorganized and strengthened NMPB and its corresponding State level Boards, in close collaboration with the National Bureau for Plant Genetic Resources (NBPGR), should prepare detailed biodiversity registers, especially identifying indigenous and traditional uses of the germplasm. The need of the hour is to document the indigenous knowledge related to Indian herbs and plants and their medicinal and other uses and convert it into easily navigable computerized databases for easy access.

4.5.15.4 An inventory of raw materials used by the industry needs to be built up. The state government should make the listing of raw materials (medicinal plants) consumed by each manufacturer within its domain mandatory. This will help in determining those medicinal plants that are in high demand and also establish a case for cultivation of those plants that are on the verge of extinction. This information can then be integrated at the national level.

4.5.15.5 With the thrust on creating village knowledge centers across the country, SHGs of medicinal plants may be formed in biodiversity rich areas, and rural youth trained in information and data management system. Necessary hardware and connectivity should be provided by the public sector in the early stages, which in due course of time should be supplemented by the private sector and financial and banking institutions.
4.5.16.0 **Financial requirement**
The TF Report on MP had in 2000, recommended an allocation of Rs.1000crore for development the sector. It is recommended that an equivalent amount be made available to the proposed National Mission on MAPs in order to enable it to launch a dynamic programme in the areas of conservation, cultivation, scientific validation, and marketing under distinct brand names. To quote the TF report on MP: “a comprehensive package of assistance and incentives is needed to promote medicinal plant sector as a thrust industry, on the lines of gems, jewellery and info-tech”.

4.5.17.0 **Acknowledgements**
A two-day consultation on Sustainable Management of Medicinal Plant Resources with the different stakeholders – medicinal plant cultivators, research institutes, government officials, industry, bankers and NGOs, was organised in Bangalore in collaboration with the Foundation for Revitalization of Local Health Traditions (FRLHT) and the University of Agricultural Sciences, Bangalore, to deliberate on the core issues facing the sector and the steps needed to address them. Special thanks are due to FRLHT for giving their comments on the paper.
CHAPTER - 4.6

ENHANCING PRODUCTIVITY, PROFITABILITY, STABILITY AND SUSTAINABILITY

ORGANIC FARMING

4.6.1 There is a growing interest in organic farming practices in several parts of India, partly due to an expectation of higher prices for organically produced farm commodities. Some states like Uttaranchal would like to be known as an “Organic Farming State”. The National Academy of Agricultural Sciences (NAAS) has issued a Policy Paper on Organic Farming, which concludes that while synthetic pesticides can be avoided, complete exclusion of fertilizers may not be advisable under all situations. NAAS recommends that “a holistic approach involving Integrated Nutrient Management (INM), Integrated Pest Management (IPM), enhanced input use efficiency and adoption of region – specific promising cropping systems would be the best organic farming strategy for India.” To begin with, the practice of organic farming should be for low volume, high value crops like spices, medicinal plants, fruits and vegetables. NAAS has also emphasized the need for intensive research on soil fertility and plant health management and on issues relating to microbial contamination of food arising from the use of farm yard manures. (Organic Farming: Approaches and Possibilities in the context of Indian Agriculture, Policy Paper 30, NAAS, February 2005).

4.6.2 The Tenth Five Year Plan provides for the establishment of a National Institute of Organic Farming and Certification. Internationally acceptable certification standards and institutional structures are urgently needed. The International Federation of Organic Agriculture Movement (IFOAM) is the leading international organization which sets the guiding principles for organic farming. IFOAM has defined organic agriculture as follows:

“Organic Agriculture includes all agricultural systems that promote environmentally, socially and economically sound production of food and fibers. Recycling nutrients and strengthening natural processes help to maintain soil fertility ad
ensure sustained production. Pests and diseases are controlled with naturally occurring means and substances according to both traditional as well as modern scientific knowledge. Organic agriculture excludes synthetic fertilizers and pesticides, and genetically modified organisms”.

4.6.3 In order to develop a well-defined strategy for helping farm families take to organic farming, particularly in medicinal and horticultural plants, NCF organized a consultation with IFOAM in March 2005, at the M S Swaminathan Research Foundation, Chennai. Dr Bernward Geier, Dr Beatrix Tappeser and other leading foreign and Indian experts participated in the consultation.

4.6.4 The main principles of organic farming are the following:

To work as much as possible within a closed system, and draw upon local resources

i. To maintain the long-term fertility of soils
ii. To avoid all forms of pollution that may result from agricultural techniques
iii. To produce foodstuffs of high nutritional quality and sufficient quantity
iv. To reduce the use of fossil energy in agricultural practice to a minimum
v. To give livestock conditions of life that conform to their physiological needs and to humanitarian principles
vi. To make it possible for agricultural producers to earn a living through their work and develop their potentialities as human beings

4.6.5 The basic focus of organic farming should be first, to produce farm products for the home market; and second for the export market when there are prospects for obtaining a premium price. The global market for organic food is estimated at US$ 30 billion of which India has currently less than 0.1% market share. It will be useful to prepare Organic Farming Took Kits, based on IFOAM principles, to assist farmers on the do’s and dont’s relating to the production of organic farm produce. It is also desirable to promote the formation of Small Farmers’ Organic Agriculture Estates to confer the power of scale at the production and post-harvest phases of farming for farm women and men owning small holdings. It will also be necessary to develop and introduce low cost but nationally and internationally acceptable certification standards and procedures.

4.6.6 There are a large number of farm families practicing organic farming in different parts of the country. There are also local level organic farmers’ associations. It will be advisable to organize a National Federation of Organic Farmers’ Associations on the pattern of IFOAM. Farm schools on the lines recommended by NCF in its first report also may be established in the farms of outstanding organic farmers. Farmer to farmer
learning on organic farming procedures through the establishment of such Farm Schools as well as through the establishment of Organic Farmers’ Clubs will be useful, since organic farming is not defined by what we do not do, but by what we do. Diverse certification procedures cause confusion and hence National Certification mechanisms and agencies are essential.

### 4.6.7 Constraints and Opportunities

**4.6.7.1** Indian soils are both hungry and thirsty. The great challenge in organic farming is the maintenance and enhancement of soil productivity through the provision of the needed macro- and micro- nutrients. How can we ensure that yields do not go down affecting adversely the marketable surplus available to small producers? The Chinese model of integrated organic and inorganic farming is ideal for small farmers but this is not acceptable to IFOAM. IPM and INS procedures which do not include mineral fertilizers or chemical pesticides are however acceptable. This will call for more research on biopesticides, bio-fertilizers, herbal pesticides and genetic resistance. **There is need for greater investment on research relating to the development of the biological software essential for linking crop productivity and quality in organic farming. In particular, there is need for more research on soil health enhancing efficient fauna and micro-organisms.** In this context, ICAR should develop high accuracy, low cost and rapid result giving soil-testing procedures based on nano-technology.

**4.6.7.2** Genetically modified crops are presently excluded from organic farming by IFOAM. Like China, we may have to keep an open mind on this issue. A blend of Mendelian and Molecular breeding and pre-breeding and farmer participatory breeding may help to combine the beneficial features of organic farming and Recombinant DNA technology particularly in staple crops. Our National Agricultural Research System will have to develop **bio-organic farming methodologies**, which can help to enhance productivity without associated ecological harm, by integrating the best in frontier science with the best in traditional wisdom.

**4.6.7.3** Presently, Indian farmers are not getting premium prices for organically grown farm communities. There is need for greater consumer education. For convincing consumers, the nutritional and health advantages of organic foods will have to be clearly
established. The highest priority will have to go to natural method of pest management, since pesticide residues in water and food are becoming major public health problems. The research back-up at present for successful organic farming is inadequate. Organic farming needs even greater research support than chemical farming.

4.6.7.4 Under our conditions, higher productivity and better quality are both essential. Krishi Vigyan Kendras can organize special training programmes for explaining to farmers the dos and don'ts relating to organic agriculture. Organic Farming Zones can be promoted under the National Horticulture Mission for fruits, vegetables, tea, spices and medicinal plants, so that certification and quality control become easy. Cost of certification also has to come down, to enable small farmers to get certification.

4.6.7.5 Above all, more market research is needed. Small farmers, who may lose to some extent in yield by not applying mineral fertilizers, should not suffer in income due to lack of higher prices in the market. Organisations like the Spices Board are doing good work in helping small producers grow organic spices for the export market. High value products like basmati rice, will benefit further in relation to net return, if they can also be marketed as genuine Organic Basmati Rice. Organic Cotton Cultivation has been successfully popularized in Maharashtra. The Maharashtra experience needs to be replicated in other cotton growing areas.

4.6.7.6 IFOAM’s principles are based both on ethical and scientific considerations. In the Indian context, priority to organic farming will have to go both to horticulture and plantation crops as well as to crops like cotton where heavy doses of chemical pesticides are applied. Medicinal plants should be cultivated only by organic methods. Ultimately, income enhancement and work security for farmers, and nutritive quality and freedom from pesticide residues for consumers should be the bottom line of all agricultural technologies.

4.6.7.7 Small farmers practicing crop-livestock mixed farming are able to take to organic farming more effectively than those who have no farm animals. In Assam and Northeast India, there is heavy rain during May-September (Southwest Monsoon period). Fertilizer application results in considerable leaching losses and hence farmers avoid
making investment in mineral fertilizers during the monsoon season. Therefore, this season is ideal for raising organic rice and other crops. Similarly, there are opportunities for developing Andaman and Nicobar Islands into organic farming islands. **It would be useful to develop a national strategy for organic farming, specifying regions, crops and seasons, ideal for raising crops through organic farming techniques.** Thus, research, extension and capacity building activities in relation to organic farming need considerable strengthening. Ultimately, net income per hectare will determine farmers’ continued interest in organic farming.
CHAPTER - 4.7

ENHANCING PRODUCTIVITY, PROFITABILITY, STABILITY AND SUSTAINABILITY

BIOFUELS

4.7.1 There has of late been much interest among farmers and State Governments in exploring the economics of growing plants like Jatropha and sugarcane for the production of bio-diesel and bioethanol. Farmers’ organizations have to get proper extension advice on the advisability of shifting their land use to the cultivation of crops for bio-fuel production. A well-defined Biofuel policy based on science and economics needs to be developed jointly by the Ministries of Agriculture, Rural Development, Petroleum, Non-Conventional Energy Sources (MNES) and Science and Technology. ICAR and CSIR will have to be actively associated. Based on a detailed discussion with experts in this field, we wish to offer the following suggestions -

4.7.2 There is a growing oil intensification of the Indian economy and more than 70% of the oil used in the country is imported. The oil import bill is over 3% of GDP and is likely to increase further, since crude oil prices are projected to rise to as much as US $ 90 per barrel. Hence, we have to step up our efforts in mobilizing both nuclear energy and all forms of non-renewable energy sources. Bio-fuels derived from plant-based resources assume importance in this context.

4.7.3 International Scenario

Among the major countries in the world in bioethanol production, Brazil is a front-runner, and has been using with gasoline, 22% ethanol blend produced from molasses and sugarcane juice. USA uses corn as the main source of bioethanol. Thailand uses sugarcane as well as cassava for ethanol. Japan, Germany, Canada, Australia, Indonesia, South Africa, Sweden are the other leading countries using ethanol blends. Bio-diesel is being used in USA, Austria, Finland, France, Germany, Greece, Czech Republic, Ireland, Italy, Spain and Sweden. The main sources of bio-diesel in these countries are rapeseed, sunflower, olive oils, which are however edible oils and are not appropriate in the Indian context, where we are importing nearly 50% of our edible oil requirements.
4.7.4 Indian Scenario

Use of ethanol as automotive fuel was first made in Mysore in 1938. Dual fuel operation in diesel engines was experimented at the Indian Institute of Science (IISc), Bangalore, in 1950. Oil crisis in the seventies, prompted the Government to test performance of ethanol-gasoline blends in cars, scooters, three wheelers and tractors in the 1980s. Methanol diesel blends were successfully demonstrated in DTC buses during 1986-92, followed by 93 Government vehicles using 10% gasohol during 1993-95 under a MNES R&D project. R&D in bio-diesel has taken up at IIT Delhi, IOC(R&D), IISc. Bangalore, Tezpur University, IIT Chennai etc. Ministry of Petroleum and Natural Gas have taken up pilot projects on 5% ethanol blends in gasoline in nine States since January, 2003.

4.7.5.0 Plants of Potential Value

4.7.5.1 The major source of bio-diesel in India is non-edible oil seeds. The technology for production is indigenously available. Bio-diesel provides bio-degradability, non-toxicity and is sulphur-free. The oxygen content is about 10%, which gives better emission characteristics in terms of CO, HC & PM.

4.7.5.2 The production potential for bio-diesel is nearly 20 million tonnes per annum. Only a few million tonnes have been utilized (due to lack of demand). Also from about 100 varieties of oil seeds, only 10-12 varieties have been tapped so far. Non-edible oils are being tested for production of bio-diesel. Estimated potential varies from 0.1 to 20 million tones, out of which 20 to 25% has been utilized. More than 100 non-edible oil bearing trees exist in India.
4.7.5.3 The important potential tree species for bio-diesel in India are as follows:

<table>

4.7.6 National Bio-diesel Strategy

4.7.6.1 Bio-diesel can be made from both, virgin or used vegetable oils (edible and non-edible). Bio-diesel needs no separate infrastructure for storage and dispensing as the existing facilities can be used. Also handling bio-diesel is safer. In addition, plantations of *Jatropha* and *Pongamia* would lead to gainful utilization of wasteland, of which there is more than 50 million hectares in the country. At a national level, a bio-diesel programme has the potential to create employment opportunities on a large scale, particularly in rural areas in the various activities along the production-use chain, such as growing plants, collection of oil-bearing seeds, extracting oil from the seeds through expeller units, trans-esterification for making bio-diesel for blending and use with conventional diesels for distribution at retail outlets. A systems approach is necessary for ensuring that the different components of bio-diesel programme are effectively coordinated and bio-diesel becomes a cost effective alternative.

4.7.7 Research, Extension and Demonstrations

4.7.7.1 The yield from the petro-plants need to be significantly increased and the efficiency of trans-esterification also has to be significantly enhanced, so that the bio-diesel production becomes economically viable. For this purpose, there is urgent need of
creating interdisciplinary research groups including agronomists, biotech researchers and energy technologists who could work together in the thrust areas for R&D, such as: genetically modified high yielding petro-plants, design and development of continuous Bio-diesel reactors, improving process efficiency and energy optimization for decentralized production.

4.7.7.2 Demonstration activities on bio-diesel currently under progress in the country include programmes of MNES. The Ministry of Petroleum including IOC has also entered into a MoU with Indian Railways for a study on the complete value chain of bio-diesel. In line with this, IOC has taken up plantation on 70 hectares of Railway land at Surendra Nagar in Gujarat. More than one lakh saplings of Jatropha have been planted at the site. Tests have been conducted with 5 percent, 10 percent and 20 percent blends of Jatropha bio-diesel in diesel, on diesel locomotive engine for power specific fuel consumption, firing pressure and exhaust gas temperatures. Trial runs on Shatabdi and Jan Shatabdi Express trains have been carried out with 5 percent and 10 percent bio-diesel. IOC has jointly with Haryana Roadways, also launched field trials on 40 buses of Gurgaon depot in April, 2004,

4.7.8 National Mission on Biofuels

4.7.8.1 The Planning Commission in coordination with various Ministries and Agencies prepared a Report on Biofuels in 2002-2003, which has proposed a National Mission on Biofuels from Jatropha plantations. A Detailed Project Report has also been prepared for this Mission and the Ministry of Rural Development has been assigned the task of implementation with the following targets: By 2006-07, Jatropha cultivation on 2 lakh ha of degraded forest land and 2 lakh ha of non-forest land, to yield 5% bio-diesel blend with petroleum diesel; 20% blend is proposed by 2011-12. However, the detailed project report for this mission is still under the process of finalisation and the mission is yet to start. Meanwhile, various activities focused on Bio-diesel, are being taken up by other Ministries, including in particular Ministry for Agriculture, Ministry of Petroleum and MNES.

4.7.8.2 As stated above, a number of Ministries and Agencies both in the public and private sectors are working on different aspects of biofuels including bio-ethanol and biodiesel. The Ministry of Petroleum including the oil companies under it and in particular IOC (R&D) have been active in carrying on demonstration trials effect of biofuels on engine performance. The Ministry of Non-Conventional Energy Sources has been taking up R&D and Demonstration Projects on technologies for conversion of fuel stock into biofuel and the utilization of the biofuel for different end users. MNES has taken up a Village Demonstration Project in selected villages to demonstrate the use of biofuels in stationary engines. The Department of Science and Technology, Department of Scientific and Industrial Research & CSIR have been also active in technology development in commercialization of different aspects of Biofuel technologies. The Department of Biotechnology is taking up activities for genetic engineering for increasing yield and quality. Ministry of Environment is focusing on afforestation as well as environment issues.

4.7.9 Need for Convergence and Synergy in Technology, Public Policy as Sectoral Responsibility

4.7.9.1 If we wish to make speedy and steady progress, there is no alternative except to bringing about integrated action among various Government Departments and research agencies. The Ministries / agencies which should work together are indicated in table 2 below:
<table>
<thead>
<tr>
<th>S.No</th>
<th>Action</th>
<th>Partners</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>Identification of seeds and developing suitable methods for extraction of oil from them and processing them to convert to biofuels, blending of biofuels; and modification in engine technology, use of biofuel as transport fuel, evolving methods to use rotten and excess food grains for ethanol production; developing policy frame work.</td>
<td>ICAR, CSIR, Ministry of Non-Conventional Energy Sources, Ministry of Science and Technology.</td>

</tbody>
</table>
4.7.9.1 Ensuring the Sustainability and Success of the Biofuel Programme

4.7.10.1 Farmers need to be assisted to undertake farming of crops used in ethanol and other biofuels, by ensuring purchase of these products at a minimum support price by government and industrial units, educating them about the species for biofuels, and cultivation techniques, and providing them with high quality seeds/saplings etc. Quality control and certification of the planting material are urgently needed.

4.7.10.2 Suitable mechanisms need to be developed to collect and store agri-residues such as rice straw, so that these wastes which are otherwise burnt, become a commercial commodity for farmers and would be available for ethanol production. This should be supported by developing the necessary industrial infrastructure to process the collected biomass for production of ethanol/other biofuels and the by product industrial wastes so generated, could be used as manure.

4.7.10.3 Use of wasteland may be encouraged to develop plantations of neem, karanja, jatropha and other such species for bio-diesel production. Mechanisms need to be developed to collect oilseeds from forests. The wood generated from plantations could be utilized as feedstock for wood gasification to generate electricity. Wasteland should be used as collection centres for agri-residue. This process will have multiple benefits like land reclamation, employment generation, decentralized electricity generation etc.

4.7.10.4 Extensive support needs to be provided to R&D institutions to work on developing suitable process development for biofuels from various feedstock and for developing agronomic practices for growing crops for biofuels in wasteland. ICAR and CSIR should jointly undertake this function in cooperation with State Agricultural Universities.

4.7.10.5 Panchayati Raj institutions have a major role to play in creating awareness among people about Jatropha and other species, for cultivation in wasteland, common land and farm hedges. Panchayats/clusters of Panchayats have to be identified for this purpose. There is need for collaboration with State and Central Government organizations - National Seed and Vegetable Oil Development Board, National Dairy Development Board etc.
4.7.10.6 Industrial sector needs to be encouraged to increase ethanol production from all available feedstock such as cereals, agri-residues, and starch-based crops besides optimizing the present level of production from molasses. The production of bio-diesel from various non-edible oils seeds also needs to be encouraged. For this purpose, necessary incentives such as soft loans for establishing new industries, updating existing industry and tax holiday, need to be provided.

4.7.10.7 In order to accomplish these tasks a 'National Biofuel Board' may be set up. The Board should develop a Roadmap for use of biofuels in petrol and diesel engines in a time bound manner besides taking necessary steps to introduce the policy measures, some of which have been proposed above. The Board should be supported with appropriate financial resources.

4.7.11 Farmers’ Perceptions

4.7.11.1 Farmers are getting confused signals about the economic viability of the programmes suggested to them. They are not sure about the quality of seeds / planting material given to them. They are not yet clear whether there will be a buy back arrangement on terms favourable to the growers. Factors relating to cost, risk and return determine farmers’ acceptance and enthusiasm in relation to new programmes. The sooner a farmer-centric National Biofuel Board comes into existence with the active support and participation of all stakeholders, including farmers’ and women’s organizations, the greater will be the prospect for making progress at the speed the country needs urgently to ensure economically affordable energy security.

4.7.11.2 The success or failure of the Biofuels programme will depend on our ability to ensure that the processing units are able to source the required quantity of raw material at the right time, in right quantities and at economically viable prices. Many dedro-thermal plants have failed because of inadequate linkages with raw material supply. The feedstock for the biofuel industry has to come from agriculture. Unless the interests of biofuel farmers are protected, the investment made at the processing end will go to waste.
4.7.11.3 We, therefore suggest that the proposed **National Biofuel Board** may have the following composition:

**Chairperson:** The Member, Planning Commission, in charge of Energy

**Members:**
- Member (Agriculture) in charge of feedstock production
- Member (Processing and quality control)
- Member (Marketing, industry-farmer linkages through contract purchase etc.)
- Member (Centre-State coordination, linkages with private sector, global technology watch)

4.7.11.4 A Board of the above kind may function like the Atomic Energy Commission with specific targets, autonomy and accountability. It can then attend to bio-feedstock production, use and marketing in an integrated manner with benefits to both farmers and the country.
CHAPTER 5
AGRICULTURAL MARKET REFORMS

5.1 Agriculture marketing includes all activities in the movement of agricultural produce from farm where it is produced to the consumers/industries and trade as per the demand. This covers physical handling and transportation, initial processing and packaging, grading and quality control for sales transaction for meeting the requirements of the different consumers/users and storage. Marketing plays the vital function of providing an outlet for the produce of the farmers and a supply line to the consumers/users. An efficient marketing system is essential for the development of the agriculture sector, providing incentives to the farmers for commercialization, increasing production and giving appropriate signals for production planning and research activities. It should encourage competition among the traders and protect the interest of the small and marginal farmers whose bargaining and holding capacities are limited.

5.2 In an agrarian economy like India, the fluctuations and the levels of prices of farm produce have considerable impact on the growth of production, the inter-sectoral distribution of income and the purchasing power with the majority of the rural population, which to a large extent determines the growth trajectory of many industries. The Government have, therefore, to constantly watch and intervene, when necessary, in the matters concerning agriculture marketing.

5.3 Some of the characteristic features of the agricultural produce marketing in India at the time of Independence were (a) sales immediately after harvest mainly for meeting the cash needs – mostly distress sale at discounted prices, sale of ungraded produce, loose carrying of the produce and lack of on-farm storage facilities (b) predominant role of the village trader and inter locking of credit and commodity market (c) Use of unstandardised weights/measures by the traders and high market charges which included charges like ‘mudat’ ‘dharmada’ ‘arähat’ etc. (d) direct sale by farmers and absence of farmers’ organizations to reach volumes and protect the interests of the small producers.

5.4 Three basic requirements for building a sound agricultural economy are a productive technology package, efficient delivery of services alongwith remunerative and stable market prices for the produce. One has to remember that the market could inflict
underserved losses on the farmer, even when he had applied modern technology and produced efficiently. This is more so now. Presently market led production is the key to an efficient production system. Better prices and larger surpluses would come to the producers who understand the market better and produce what the customers want. The situation was different at the time of Independence when the economy was less open, there was shortage of production against demand and the customers did not have much choice. At that time, the important issue was to save the farmers from the malpractices of the traders and facilitate growth and development of an orderly marketing arrangements.

5.5 In view of the above, after independence, the Government introduced various measures broadly covering the development and extension of marketing network and the actual regulation of the conduct of market. Government interventions covered not only market yard but also trading, stocking, quality maintenance, grading etc. Measures were also introduced by the Government for intervention in prices, procurement and also in import and export of agriculture commodities. Various instruments of fiscal and monetary policies of the Government also impact the cost of performing various marketing functions including transportation, stocking and trading in the markets.

5.6 Organized marketing was promoted through a network of regulated markets. A massive programme for creation of the marketing network was taken up. As on 31st March 2004, as many as 7418 markets had been brought under the ambit of regulated markets. Most of these markets are wholesale markets. In addition, out of 27,294 rural periodical markets [village haats, shanties etc], nearly 15% function under the regulated framework. The basic objective of setting up the network of markets was to protect the interests of the farmers and eliminate various malpractices of the traders. Fair play and transparency in transactions was aimed at. Most of the State Governments and the Union Territories enacted legislations (APMC Act) to provide measures for development of agriculture produce markets.

5.6.1 In view of the supply side constraints, the need for orderly functioning of the markets and protecting the interests of the producers and consumers, besides the APMC Acts various other legal enactments were promulgated by the Centre and the State Govts. These included the following:
Prevention of Food Adulteration Act, 1954
Essential Commodities Act, 1955
Standards of Weights & Measurement Act, 1976
Prevention of Black Marketing & Maintenance of Supply of Essential Commodities Act, 1980
Consumer Protection Act, 1986
Bureau of Indian Standards Act, 1986
Agriculture Produce (Grading & Marketing) Act, 1986

5.6.2 In addition, there are also specific orders covering various products like meat, vegetable oils, milk & milk products, fruit and fruit products, pulses, edible oilseeds, edible oils, solvent extracted oil, deoiled meals etc. The recourse to the provisions under these orders etc is mainly intended to be given during periods of scarcity and to stop the malpractices. Some of these orders also cover activities like storing, packing, quality, blending, processing etc. The Government of India also regulates future trading in agricultural commodities. These Acts and orders were promulgated during periods of scarcity and have perhaps outlived their utility. These need a revisit and may be scrapping in many cases.

**Box-1**

**Essential Commodities Act**
The multiplicity of Acts and Government orders for regulating the conduct of market functionaries and processing units is not only restricting competition among those who deal and ultimately buy farmers’ produce but also increase the transaction cost for marketing operations. There is a need to review the Essential Commodities Act and other legal instruments, which impact the marketing and processing activities. The Task force on Employment Opportunities (Planning Commission 2001) had observed ‘The Essential Commodities Act is a central legislation which provides an umbrella under which the States are enabled to impose all kinds of restrictions on the storage; transport and processing of agricultural produce. These controls were traditionally justified on the ground that they were necessary to control hoarding and other type of speculative activity, but the fact is that they do not work in times of genuine scarcity and they are not needed in normal times. Besides, they are typically misused by lower level of administration and become an instrument of harassment and corruption’.

_Tenth Five Year Plan Document [Para 7.8.11]_

**5.7.0 Strengths of the Regulated Marketing System**

5.7.1 The main strength of the agricultural produce marketing system, in India is the huge network of markets. As on 31st March 2004, as many as 7418 markets were under the ambit of the regulated markets. Most of these were wholesale markets. In addition, out of
the 27,294 rural periodical markets, about 15% functioned under the regulated framework. The regulated markets, have also achieved certain amount of success in providing transparent transactional methods/marketing practices, basic amenities and services conducive to an efficient marketing system. Some of the developments in the marketing system at the primary market level and farmers marketing practices are: [a] The marketed surplus per farm has gone up. The overall marketed surplus-output ratio is estimated to have improved from 33.4% in 1950-51 to 64.1% in 1999-2000 [b] There has been some standardization of market-charges and the liability has generally shifted to the buyers [c] The quality of market information, available is much better than what it was during the ‘fifties and sixties’ [d] The market sales have increased [e] There are sectors where sales through the cooperative or groups are substantial [f] Inspite of the restrictive features, the system has made space for contract farming/direct marketing /other innovative practices like ITC’s e-choupal etc.

5.7.2 According to a study [1991] the expenses of the farmers in respect of commission, weighing, hamali, brokerage etc, for marketing their produce came down by about 50%. In a recent study done by the Karnataka State Agriculture Prices Commission [2002] in respect of 3408 farmers, revealed that about 29% of the sample farmers sold their sample produce through the regulated markets. The farmers cited competitive prices [52.4%] correct weighment [20.1%], easy and early payment [12.4%], quick transaction [1.5%], and no buyer at village (4%) as reasons for their using the regulated markets. It was also revealed by the above study that the farmers received higher prices in respect of Paddy, Soybean, Ragi, Greengram, Bengalgram and Groundnut by selling in the regulated markets. However, in case of Tur, the highest price was at the farm gate, where as in the case of Maize and Jowar, the farmers selling in the rural periodic market received the highest price.

5.8.0 Weaknesses of the Regulated Marketing System
5.8.1 However, inspite of the development of the regulated agriculture produce marketing system, several weaknesses such as, distress sales immediately after harvest, absence of grading and packaging at the farm level and inter-locking of credit and commodity markets continued. Further, the regulated marketing system did not offer the farmers virtually any options/choices, the market charges became high and the farmers complain
about lack of transparency in weighing & auction as also the poor treatment given to them at the market yards. There is a need to have more transparency in the auction systems and curbing the manipulations of prices by the traders. The other weaknesses in the present marketing system are listed below:

- Thin spread of the regulated markets in many States
- Inadequate development of the rural periodic markets which are the first contact point for the growers
- Inadequate infrastructural facilities at the regulated markets.
- Large variations in the market fee/charges across the States
- Variations in the entry tax/octroi and sales tax
- Lack of transparency in auctions and other trade related activities
- Failure to develop a common trade language
- Inefficient working environment

5.8.2 The Karnataka study (2002) referred to earlier, indicates that inspite of better prices in the Regulated Markets, nearly 71% of the sample farmers chose not to sell at the regulated markets.

It is clear from the above findings that the regulated markets could have performed better with more developmental efforts and professional management. The APMCs and the State Agriculture Marketing Boards also need to pay more attention to curb manipulations in the marketing system. Coupled with the fact that only around 29% of the sample farmers used the regulated markets is a sad commentary on the performance of the APMCs/ Market Boards.

**Box-2**

**Regulated Markets- Karnataka**

The major operational weaknesses at the Mandi are [a] existence of malpractices such as unauthorized charging of commission from the farmers, considerable amount of produce taken away as sample, arbitrary deduction from the weight and lack of transparency in transactions. [b] Bureaucratisation in the management of regulated markets has prevented them to become farmer-friendly institutions. It is understood that more than 80% of the market committees have been superceded. [c] The traders, commission agents, other functionaries including weighmen / hammals /coolies etc. have in many places formed strong associations and do not allow entry of new persons. [d] While most of the APMCs and the SAMBs are financially well placed, adequate investments in the development/improvements/modernization of the market yards have not been made. There are instances where the funds have been diverted to the Government accounts. [e] Adequate investment in development of rural primary markets [haats/shanties etc.], which are the first contact point for the farmer, have not been made.

The farmers feel that there should be arrangements for supply of their daily domestic requirements and key inputs required for cultivation in the Market Yard itself. To improve the operations at the Mandis, it may be useful to have a more broad based board consisting of representatives of genuine farmers, traders and even commission agents. Holding of regular election of market committees and State Agriculture Marketing Boards are also equally important.

*Extracts from the Report of the study done by Karnataka State Agriculture Price Commission-2002*

5.8.3 The variations in market charges and taxation in different State/UTs is shown at Appendix I. The taxes and levies charged in certain states on the primary transactions are very high. In Punjab, it worked out to 11.5% and Haryana 10.58%. Some States also levied ‘Rural Development Cess’ and ‘Infrastructure Cess’. Another issue is the present system of levy of fee at multiple points in the regulated market. An option could be to have a single point levy of market fee to cover the entire process of marketing by the farmers. The paradigm of efficiency in marketing and produce handling rests on the reduction in the transaction cost.
The complex tax structure and multiplicity of state-level taxes distort the process of trade and marketing. Inter-state and Centre-State harmonization of tax laws and their administrative systems can facilitate the simplification of the tax regime. Octroi on transport of goods, where still in force, needs to be looked at and phased out. The permit system for the transport vehicles [issue of national permit] needs to be reviewed. The harassment to which the operators are subjected to [insistence on showing the drafts paid for obtaining the national permit or demanding payment for tax and fee at the border check posts.] needs to be curbed. The move towards a nation-wide uniform value added tax [VAT] is desirable. VAT is a multi-stage tax, which is levied on the value added at each stage. As each input going into final product is taxed only once, this tax avoids cascading and multiple incidences, and should be easy to monitor and implement. The state VAT, with a harmonized rate structure across the states, could replace all other sales taxes and other taxes like turnover tax, octoroi and entry tax etc.

Tenth Five Year Plan Document – Chapter -7.8

5.8.4 The major constraint of the regulatory framework of the agricultural produce marketing system is that it discouraged investments by the private sector, allowed certain monopolistic practices to develop and generally discouraged free trade and competition. It is surprising to note that a processor has to pay a fee on commodities brought into the notified area for processing without any service/value addition by the regulatory authority. In the present arrangement the farmers have no choice. In case they want to sell their produce in the wholesale market, they have to come to the regulated markets. Absence of choice and competition has adversely affected the development of markets and interest of the farmers and consumers in the changed circumstances.

5.9.0 Marketing Infrastructure - Amendments to the APMC Act, etc.

5.9.1 Let us now look at the marketing infrastructure for the agricultural produce marketing in India. The infrastructure is important for performance of various marketing functions, broadening and deepening of the market and also transfer of appropriate price signals for improving the marketing efficiency. As already stated, there are 7418 markets under the ambit of regulated markets. This works out to one market for 459 Sq. Kms. In Assam the coverage for each market is 2257 Sq. Kms followed by Himachal Pradesh [1600 Sq. Kms.], Orissa [1053 Sq. Kms], Rajasthan [830 Sq. Kms], Madhya Pradesh including Chattisgarh [719 Sq. Kms], Gujarat [490 Sq. Kms.], Tamil Nadu [481 Sq. Kms], Uttar Pradesh including Uttaranchal [476 Sq. Kms]. The thin spread makes it difficult for the farmers to bring their produce to the regulated market particularly in areas where the road connectivity is not upto the mark. The need is to give a greater
focus to the development of rural periodic markets, which are the first contact point for the farmers. The States where the coverage was better than the all India average were Punjab [74 Sq. Kms], West Bengal [152 Sq. Kms], Haryana [155 Sq. Kms], Bihar including Jharkhand [214 Sq. Kms], Andhra Pradesh [319 Sq. Kms], Maharashtra [359 Sq. Kms] and Karnataka [406 Sq. Kms]. Infrastructural facilities help in reduction in marketing costs, which help in improving the realisation of the growers and reducing the price, which the consumer pays. The infrastructural facilities in most of the regulated markets are inadequate. The table below indicates the lack of facilities at these markets.

5.9.2 The Directorate of Marketing and Inspections, Government of India have established Central and Regional laboratories for certification under the AGMARK system. So far, grade standards have been notified for 164 commodities. During, 2003-04 (upto December) commodities valued at about only Rs.3525 crore were graded for
internal trade and about Rs.30 crore for export purposes. Standardization and appropriate grading arrangements/facilities are important. While for exports, the grading according to laid down standards is compulsory, for commodities sold in the domestic markets, grading has remained voluntary. **This is a serious bottleneck in our market system, which necessitates sale of individual farmer’s lot leading to delays and exploitation in pricing and also makes scientific and transparent auction system difficult to introduce.** It may be necessary to have quality standards for all agricultural commodities and compulsory grading system may be introduced in a phased manner.

5.9.3 The Inter-Ministerial Task Force on Agriculture Marketing Reforms, which gave its Report in May 2002, observed as under “High investments and entrepreneurial skills are required for creation and management of the agriculture marketing infrastructure. The situation of control by the State has to be eased to facilitate greater participation of the private sector, particularly to engender massive investments required for the development of marketing infrastructures and other supporting services. Investment requirements for the development of marketing, storage, cold storage infrastructure in the country during the Xth Plan has been estimated to the order of Rs.12, 230 crore.”

5.9.4 The Task Force further observed that in order to encourage private sector to make large investment for developing alternate marketing infrastructure and supporting services, the provision of the APMC Act would need modification to create a lawful role for the private sector in the marketing development. **There was also a need to** [a] reduce regulatory controls and simplify procedures [b] making complementary investment by the State and Central Government [c] providing subsidy to the private sector initiatives to attain economic viability [d] ensuring adequate credit flows to agriculture marketing and [e] declaring the market development projects as ‘infrastructure projects’ within the meaning of Section 10(23G) of the Income Tax Act. To attract promoting agencies to take up infrastructure projects, the Central/State Governments need to additionally extend support in the allocation of suitable land to set up the markets, provision of village land for Farmers Associations and collection centers, deregulation of area from the APMC Act where new markets were to be set up, ensure fast approval of foreign technical assistance, import of equipment and for services like electricity, water, sewage, telephones, etc. The Task Force also felt that the Central Government support for investment in market infrastructure might be linked with deregulation and reforms in the agriculture-marketing sector.

5.9.5 Following main amendments in the APMC Act were suggested: -

- Enabling private and cooperative sectors to establish and operate (including levy of service charge) agriculture marketing infrastructure and supporting services.
- Direct marketing of agriculture commodities from producing areas and farmer’s fields, without the necessity of going through licenced traders and regulated markets.
- Permitting ‘Contract Farming’ programmes by processing or marketing firms. Incidence of taxes by way of market fee, cess, duties, taxes etc. on procurement of agriculture produce under the above programme be waived or minimized.
- Rationalisation of levy of market fee by introducing single point levy of market fee in the entire process of marketing in the State

5.9.6 The progress in amendment of the APMC Act in different States and the Union territories is given at Appendix II. It would be seen that there is no APMC Act in Kerala,
Manipur, Andaman & Nicobar, Dadra & Nagar Haveli, Lakshdweep and Daman & Diu. In case of Tamil Nadu, the Act provides necessary reforms and hence no amendment is required. Madhya Pradesh, Himachal Pradesh, Sikkim, Andhra Pradesh, Nagaland have made the requisite amendments. In the case of Maharashtra, Rajasthan, Haryana, Karnataka, Gujarat, Punjab and NCT, Delhi part of the reforms have been completed. In most of these States, further amendments are likely to come about in due course. In the case of States like Orissa, Assam, Mizoram, Arunachal Pradesh, Tripura, Chattisgarh, Meghalaya, Jammu & Kashmir, Uttar Pradesh, Uttranchal, Goa, West Bengal, Pondicherry and Chandigarh some administrative action has been initiated but the reform process would take time. In the case of Bihar and Jharkhand, the administrative work is also yet to start. **The Govt. of India is attaching considerable importance to the reform of the APMC Act and is playing a very proactive role.** However, the response from some of the state is not adequate. The Government of India have circulated a draft of amended APMC Act and the draft of agreement for Contract Farming to the States for their guidance and further action. The Agriculture Ministry also held a conference of the State Ministers incharge of Agriculture Marketing in November 2004 at Bangalore under the Chairmanship of the Hon’ble Union Minister for Agriculture for evolving a nation wide consensus on reforms in marketing sector and to accelerate the pace of its implementation. It was felt that the reforms in APMC Acts were necessary for creating a nation wide integration of the agriculture markets, facilitating emergence of agriculture markets in private and cooperative sectors and creating a conducive environment for private sector investment in the market infrastructure.

5.9.7 The Inter Ministerial Group also made certain recommendations for promotion of forward and futures markets in agricultural commodities, development of negotiable warehouse receipt system and deepening of marketing credit etc. which are discussed in subsequent paragraphs.

5.9.8 The role of the APMCs and the State Agriculture Marketing Boards [SAMBs] needs to change from regulation to development in the changed production and demand environment. The APMCs and SAMBs should be primarily involved in grading, branding and packaging and building up markets for the local products in domestic and even international markets.
5.9.9 The Government of India have also announced a reform linked Central Sector Scheme “Development of Marketing Infrastructure, Grading and Standardization” during X\textsuperscript{th} plan period. Under the scheme, assistance is available for agri-infrastructure projects to those States, who undertake suggested reforms in the APMC Act.

5.10.0 The Producer’s Perspective
5.10.1 Discussions with farmers across the country give the impression that they consider ‘market’ as a major constraint for further diversification and commercialization of their agriculture. More and more farmers have begun to realize that market led production is the key. The farmers appeared to be quite wary of the advice of the extension staff, which is generally not based on sound knowledge of the market. The present marketing arrangements, which primarily focus on regulation rather than development and innovations, is falling much below their changing expectations. In future, product-quality and specialty products are going to be important in both domestic and international markets. The extension staff and the farmers need training and guidance in maintenance of quality standards and specifications. The extension agencies/NGOs/PRIs could play a role in the knowledge dissemination. The Indian agriculture needs to move from low value agriculture to high value agriculture. There will be need to improve infrastructure for quality testing facilities [laboratories] and related infrastructure at all the levels. There is urgent need to provide extensive training to the farmers. The concept of ‘Farm Schools’ for lateral training of farmers needs to be pursued. The farmers would also need proactive advice on matters relating to land use with a clear view on the market. Such proactive advice may have to be based on meteorological, marketing and management information [taking into account soil characteristics, irrigation water availability and other agro-ecological conditions]. A restructured State land Use Boards supported by a team of technical experts/agencies could perhaps render such advice to the farmers. There have been instances where the farmers in large number switched over to certain commercial crops which did not have large enough market to absorb the increased production leading to a crash in prices.

5.10.2 In developed countries, it is fairly common for the farmers to organize themselves under the banner of the commodity that they produce. Farmers producing pulses in USA are organized under UNIGRAIN that decides about production and marketing of pulses
to obtain better prices for the pulses and links itself with producers of products made from pulses. It communicates with the Government on important policies relating to prices/tariffs etc. It also disseminates information to all pulses growers on market trends etc. Plain Cotton Cooperative Association [PCCA] in another farmer owned organization in USA. Such organizations could play an important role in developing market orientation of the growers in our country and could also generally help in articulating farmer’s issues on commodity basis. The DMI in the Agriculture Ministry could perhaps take a lead and encourage formation of commodity wise farmer’s organizations. The National Egg Coordination Committee is a fine example of the producer’s organization, which has done very well in development of poultry industry.

Box-4

National Egg Coordination Committee (NECC)

A movement of Farmers, for the Farmers

The NECC played a crucial role in promoting the production and consumption of eggs and is trying to lead the poultry sector to the path of profitability. NECC advertising campaign, which used to appear regularly on television in the early 1990s, certainly caught the imagination of the nation. A catchy tune combined with visuals was used to promote the consumption of eggs. The campaign's creativity won many accolades. But its success was really felt when egg consumption went up significantly and this benefited farmers across the country. In effect, it was farmers (more than 25000), under the banner of the NECC, who began the movement, causing a revolution of sorts. With its faith in farmers and in marketing techniques and its commitment towards the cause of agriculture, the NECC has contributed towards bolstering India's poultry sector.

In 1981, the egg industry was hit by an unprecedented crisis. At that time, traders who did not take into account the cost of production or the demand and supply situation determined the price of egg. Eggs were procured at artificially lowered prices. Once they built up enough stock, prices would be increased. During the high-price season traders did not buy eggs from the farmers. The price of egg was thus manipulated so that eggs could be bought at a low price and sold at a higher price. Obviously, this system did not benefit either the producer or the consumer. The NECC has expanded its scope to include:

- The fixing of remunerative egg prices across the country;
- Price support operations in cooperation with the National Agricultural Cooperative Marketing Federation of India (NAFED);
- Market intervention through Agrocorpex India Limited (ACIL), a marketing company with only poultry farmers as shareholders, promoted by the NECC;
- Rural market development by promoting distribution channels; Including eggs in the Noon Meal Programme for school children introduced by the government of Tamil Nadu;
- Mass communication programmes to promote egg consumption.
With an increase in demand for eggs, poultry is one of the fastest growing segments in the country. A study on the Indian food industry done by the Confederation of Indian Industry (CII) and management consultants McKinsey, says: "The poultry sector has the potential to grow at 20 per cent per annum over the next 10 years." The study has set a target of Rs.4, 80,000 crores a year by 2005 for this sector.

5.11.0 Direct Interventions in Marketing by the Government

5.11.1 Besides the administered price regime which covers declaration of minimum support price (MSP) for selected crops, statutory minimum price (SMP) for sugar cane, levy price for rice and sugar and the central issue prices for rice, wheat and coarse cereals for sale under the Public Distribution System (PDS), there is also direct entry of Government through the public agencies in the market. Stocks of rice and wheat are maintained by the State, cereals and sugar are distributed through the PDS at prices lower than the market and there are open market operations by public agencies to ensure orderly price movement of important agricultural commodities. The Cotton Corporation of India, the National Agricultural Cooperative Marketing Federation of India (NAFED), the Jute Corporation of India, the TRIFED and the state level marketing federations also undertake open market operations. In addition, the Government have also encouraged cooperative organizations to undertake marketing functions on behalf of the farmers (through these have not been much of a success except in some sectors). The Government have also been intervening in the market under the Market Intervention Scheme (MIS) in respect of commodities not covered by MSP, but on a selective basis. This role needs to be strengthened particularly in the case of sensitive commodities.

5.11.2 However, notwithstanding the direct intervention by the Government, the markets of agriculture commodities have been largely dominated by individual traders in the private sector. The private trade handles about 80% of the marketed surplus of agriculture commodities. It is estimated that there are about 20 lakh wholesalers and nearly 50 lakh retailers, which include nearly 4 lakh shops operating under the Public Distribution System. Besides the traders, the processors also enter the market. The hullers, shellers, rice mills, wheat millers, pulses (dal) mills and other processors including expellers, crushers, solvent extraction units, oil refining units etc. are the bulk buyers in the market. These processors are very large in number and operate at different levels of scale,
mechanization and efficiency. The role of processors has also increased in certain commodities. Bakeries, flour mills, dal mills, fruits/vegetable processors enter the market directly and are buying more. The consumer is also consuming more of bakery products/flour rather than buying wheat and processing it in the home or in the neighbourhood ‘Chakki’.

5.11.3 The market for fruits, vegetables, meat, poultry products etc. is also dominated by the private sector. Processed fruits/vegetables/meat products etc. still form a very negligible part of the total market. However, with increase in urban purchasing power and changing life style the market for processed food is growing and is set to grow rapidly in the coming years. Though, large companies are getting into the processed food sector, at present the sector is dominated by the unorganized sector.

5.11.4 In spite of the fact that the agriculture produce market sector has a very large number of players, due to infrastructural bottlenecks, geographically dispersed market places, absence of a well organized futures market, there are localized monopolistic tendencies and manipulations which often adversely affect the interest of growers.

5.12.0 Agriculture Price Policy
5.12.1 Agriculture price policy instruments are used to influence the level and fluctuation in prices and importantly the spread from the farm gate level price received by the producer and the price paid by the ultimate consumer. While initially, the State was mainly concerned with regulating the private traders, imports and distribution of food-grains etc. at low prices, after the mid sixties, the focus was on using the price policy for increasing the domestic production and providing food-grain to the consumer at reasonable prices. **In India, it is important to note that the producers are also the major consumers of food-grains unlike in many other countries where the farmers constitute a very small percentage of the population.** The Commission for Agriculture Costs and Prices [CACP] has a major responsibility in the matter. The CACP is required to monitor the movements in the terms of trade for agriculture sector and the fair sharing of the gains arising from the application of technology and public investment in agriculture between the farmers and the consumer.
5.12.2 The 25 commodities covered under the Minimum Support Price account for over 80% of the gross cropped area and 75% of the value of output. Some other commodities, which are not covered under the MSP, are included under the Market Intervention Scheme [MIS] discussed earlier.

5.12.3 The Govt. while fixing the level of the support price for a commodity keeps in view the various factors including (a) the cost of production (b) change in input prices (c) input-output parity (d) trend in market prices (e) demand and supply situation (f) inter-crop price parity (g) effect on industrial cost structure (h) effect on general price level (i) effect on cost of living index (j) international price situation (k) the parity between price paid and prices received by the farmers.

5.12.4 The cost of production is one of the main considerations in deciding the level of the MSP. However, it is not easy to decide the cost of production. The cost of production of the same crop varies between regions and between farmers of the same region. The CACP recommends the MSP on the basis of the weighted average cost of production in states giving consideration to the variability of the cost of production over the States, taking into account also the factors of production, paid as well as the imputed values of unpaid factors in fixed and variable cost of production. The risk factor and the marketing and post harvest expenses are however, not taken into account. The CACP could look into these aspects.

5.12.5 An important issue is the poor implementation of the MSP in all regions except Punjab, Haryana, Andhra Pradesh, to some extent UP and MP and consequently the market price often rule lower than the MSP. Further, except wheat and paddy, the MSP mechanism rarely benefits farmers of the remaining crops. **There is need for a much stronger protection of MSP in different regions of the country for all commodities.** The Eastern region needs special attention because of the widespread rural poverty in the region as also the fact that the region has considerable potential to improve productivity, if adequate care was taken regarding pricing, marketing, technology and credit support.

5.12.6 Another connected issue is the delay in issue of support price [MSP]. The announcement could influence the decision of the farmers in allocation of land and other
resources only if it is made well before the sowing season. While announcement for Rabi have been often well in time, the MSP for Kharif in the past had been delayed.

5.12.7 Not withstanding the above constraints, the MSP may have to be continued in the foreseeable future and its implementation should be improved. However, the strategies may have to change in view of the changed circumstances. We are not facing scarcity conditions and the economy is much more open than what it was earlier. The High Level Committee on Long Term Grain Policy 2002 (under the Chairmanship of Prof. Abhijit Sen has favoured the MSP around the national floor level prices with all India open ended operations. However, to protect the farmers from market risks, the above Committee suggested price and income insurance coupled with negotiable warehouse receipt system.. These developments may take time and hence the change in strategy may have to be gradual. The commodities, which are not covered under the MSP, market intervention on a selective basis also needs to be resorted to for ensuring that the prices realized by the farmers are stabilized. Price behaviour of sensitive commodities like onions, potatoes, tomatoes etc. needs to be closely watched particularly during the glut season for need based market intervention under MIS. However, the policies regarding monopoly procurement of cotton in Maharashtra, levy on rice mills etc. need to be reviewed.

5.12.8 The small and marginal farmers are more concerned about the cost of production and more particularly the cost of paid out inputs. Any strategies to minimize subsidies on inputs and compensating the farmers by allowing increase in prices would need to be examined very carefully as most of the marginal farmers in particular are likely to be net buyers of agriculture commodities. However, there is no doubt that input subsidies need a closer look and a much better focus.

5.12.9 The pricing policy has contributed towards achieving self-sufficiency in food-grains and also assisted in commercialisation and diversification of our agriculture. In spite of general criticism that populism and not economic consideration are responsible for various decisions, the Government have, to a large extend balanced sharing the gains of technology and public investment between the farmers and the consumers. However, as stated earlier, the MSP could not be effectively ensured across the country and the
prices in different parts of the country have often been lower than the MSP. Perhaps it could also be said that the price signals, research, extension and public policy together could have contributed more in improving the dryland agriculture and greater diversification and faster movement from low value agriculture to high

value agriculture in the country. It is also very important that the import tariffs on farm commodities produced in the resource poor regions (particularly dryland) like oilseeds are carefully monitored and maintained at levels to provide enough incentives to the dryland farmers.

<tr>
<th>Long-Term Grain Policy</th>
</tr>
</thead>
<tbody>
<tr>
<td>The High Level Committee on Long Term Grain Policy—2002 under the Chairmanship of Prof. Abhijit Sen had examined the various aspects connected with the Minimum Support Price [MSP] and Price Support Operations. The Committee had observed as under:</td>
</tr>
<tr>
<td>“MSP policy was critical in India’s achievement of food grains self sufficiency but is now grossly distorted. Nonetheless we are convinced that MSP policy should continue, but with immediate correction. We recommend.</td>
</tr>
<tr>
<td>1. The Central Government should announce the MSP policy before the sowing season on recommendations of the CACP.</td>
</tr>
<tr>
<td>[a] The CACP should be made an empowered statutory body.</td>
</tr>
<tr>
<td>[b] In recommending MSPs, which should apply on Fair Average Quality [FAQ] grain, the CACP should go strictly on the basis of C2 cost of production (i.e., all costs including imputed costs of family labour, owned capital and rental on land) in more efficient regions.</td>
</tr>
<tr>
<td>[c] The CACP should also indicate its estimates of A2 + FL costs (i.e., costs actually paid plus imputed value of family value labour) for relatively high cost regions.</td>
</tr>
<tr>
<td>[d] The CACP should recommend only a single MSP for paddy.</td>
</tr>
<tr>
<td>[e] The MSP, set at a floor price on the recommendations of the CACP, should have a statutory status. In particular, the responsibilities of the Central Government and obligations of the State Governments should be defined clearly.</td>
</tr>
<tr>
<td>[f] All agencies, Central, State, Cooperative or Private, which are a part of public grain management, should be legally bound by the MSP policy.</td>
</tr>
<tr>
<td>[g] If the present situation continues, where some States impose excessive levies on MSP purchase, the Central Government may announce its MSP policy by declaring a procurement price inclusive of an uniform 4% allowance for such levies over the MSP.</td>
</tr>
<tr>
<td>2. Once the Government announces the MSP, it should underwrite open-ended purchase of FAQ grains to assure the growers an adequate return to their cost. It should be the responsibility of the Central Government to make the fiscal and banking provisions necessary to enforce MSP throughout the country”.</td>
</tr>

5.13.0 Other Issues

5.13.1 With the international agriculture commodity price scenario and forecasts generally indicating stable prices during the next three-four years, there is urgency to bring about improvement in the efficiency of production and marketing to ensure that our agriculture remains competitive. Inefficient post harvest operations, infrastructural constraints, too many intermediaries, little value addition and the regulatory rather than the developmental and promotional to the marketing are some of the factors, which have been coming in the way of efficient functioning of the markets for agricultural produce. Harvesting and post harvest operations are as important as the production process itself. Unfortunately, harvesting, threshing etc. are inefficiently done, which leads to considerable loss in value. For example, the losses to the farmer in rice crop for different post harvest operations have been estimated at harvesting (1 to 2%), stacking, bundling, storing (2 to 7%), farm level haulage (1 to 3%) and drying (1 to 5%). Then, there are the milling losses of about 2 to 3 %. Storage is another serious problem in our supply chain. A Planning Commission Study showed 6.8% loss due to storage, pests and rodents [5%] and moisture/birds etc. [1.8%]. According to the National Institute of Agriculture Marketing (2000) and the study of John Moore & others (1973) the average losses under wheat, maize and pulses were estimated at 7%, 10% and 9% respectively. The post harvest and storage losses for fruits and vegetables were huge and varied between 14% (Apples) and 70% (Papayas). The losses for Citrus (57.5%) Banana (50%), Cauliflower (49%), Tomato (27.5%), Onions (25.5%) and Potato (22.5%) were quite high. The situation of storage of the perishable commodities is very unsatisfactory both regarding adequacy as well as operational efficiency. The cold storage capacity is grossly inadequate. Further, the costs of creation of cold storage facility as well as the operational costs are much higher than similar facilities, say, in the USA. Poor transportation arrangements and handling are other areas of concern particularly for perishables like fruits and vegetables. Except in few cases, fruits and vegetables are often packed in gunny bags, some times vegetables are stashed on top of each other in the trucks etc., the handling is extremely poor with the transporter refusing to accept any responsibility for proper handling leading to deterioration in quality. Bullock carts, tractors, trolleys, trucks are generally used for transportation of agriculture produce from the farm gate.
Fruits/vegetables are often transported to long distance from farms to Markets in open trucks/trolleys etc. losing quality, weight, water and even quantity all to the detriment of the grower. The constraints [other than those at the Market] could be summed up as under:

- Inefficient harvesting and post harvest handling
- Lack of storage facilities at the farm level
- Problems of proper transportation from farm to mandi, huge costs and long time involved.
- Constraints in transportation from mandi - general lack of wagons, silos and sometimes even bagging materials.

5.13.2 The PRIs/ NGOs/ SHGs could play an important role in improving the awareness of the farmers about the post harvest losses some of which could be reduced by use of slightly different equipments or simple improvements in handling the produce. There is need for introducing post-harvest technology wing in every Krishi Vigyan Kendra (KVK).

5.13.3 Another problem is the large number of intermediaries in the marketing chain. There are often 6 to 7 and sometimes even 8 intermediaries before the produce reaches the consumers. Each intermediary adds margins. Costs are involved in intermediation, which can be minimized by improving efficiency, but not eliminated. It is however, important to reduce the large margins, which are added at each stage. These margins sometimes add up to 100% to 150% without significant value addition. According to available information from various studies, the producer gets about 25% to 30% of the consumer’s price in the case of wheat, maize and rice. However, the milk producers under the ‘Anand model’ get about 60% of the final price. In fruits and vegetables, the mark ups by the intermediaries touch about 60% of the costs while the same is reportedly about 6 to 8% in the USA. High-mark up means low returns to the farmers as a percentage of the retail price and secondly the consumer pays a high price. There is a need for tightening the supply chain and eliminate some of the intermediaries. This is important and needs all efforts for promotion. Normally 3-4 intermediaries between the producer and the consumer should be able to discharge all the functions. Farmer’s own organizations (cooperatives and others) for aggregation and dealing with the Mandi level
organization would help in eliminating at least two/three intermediaries. As price received by farmers in direct sales to the consumer is better [in absolute terms and also in proportion to the price paid by the consumer] and the consumer also pays a lower price, some of the States are experimenting with ‘Farmers’ Markets’ Apni Mandi or ‘Rythu Bazaars’ for fruits and vegetables etc. These experiments and replications need to be encouraged Contract Farming, ITC’s e-choupal, SAFAL etc. are initiatives to improve the supply chain.

Box - 6

National Dairy Development Board (NDDB)

An Institution of National Importance

Due to very wide dispersal of producing and consuming units of milk, the unorganized sector continues to dominate the milk marketing in India. However, the market structure for milk is constantly changing. The organized sector now handles above 20% of the milk output in the country. The cooperative sector accounts for nearly 50% of this. There are over 1.10 lakh milk producers cooperatives federated into district milk unions and State Dairy Federations, which have organic links with the Mother Dairy at the national level. It is heartening to note that the milk producers in the Anand Model of milk production get net of intermediation, about 60% of the final price. In other basic foods, the returns are as low as 30% of the final price. NDDB supports the development of dairy cooperatives by providing them financial assistance and technical expertise. Over the years, brands in milk products created by cooperatives have become synonymous with quality and value. Brands like Amul (GCMMF), Vijaya (AP), Verka (Punjab), Saras (Rajasthan), Nandini (Karnataka), Milma (Kerala) and Gokul (Kolhapur) are among those that have earned customer confidence. The Dairy Cooperative Network i) includes 170 milk unions ii) operates in over 338 districts iii) covers nearly 1,08574 village level societies iv) is owned by nearly 12 million farmer members.

Milk Production
- India's milk production increased from 21.2 million MT in 1968 to 88.1 million MT in 2003-04.
- Per capita availability of milk presently is 231 grams per day, up from 112 grams per day in 1968-69.
- India's 3.8 percent annual growth of milk production surpasses the 2 per cent growth in population; the net increase in availability is around 2 per cent per year.

Marketing
- In 2003-04, average daily cooperative milk marketing stood at 148.75 lakh litres; annual growth has averaged about 4.2 per cent compounded over the last five years.
- Dairy Cooperatives now market milk in about 200 cities including metros and some 550 smaller towns.
- During the last decade, the daily milk supply per 1,000 urban consumers has increased from 17.5 to 52.0 litres.

Innovation
- Bulk vending - saving money.
- Milk travels as far as 2,200 kilometers to deficit areas, carried by innovative rail and road milk tankers.
- Ninety-five percent of dairy equipment is produced in India, saving valuable foreign exchange.

Macro Impact
- The annual value of India's milk production amounts to about Rs. 880 billion.
- Dairy cooperatives generate employment opportunities for some 12 million farm families.

In sum, NDDB is a unique example of an organisational innovation with a focus on human resource and co-operative development in India. By placing technology and professional management in the hands of the village societies it has helped to raise the standard of living of millions of poor people. These processes prove that true development is the development of the people and this could be achieved through putting the instruments of development in the hands of the people.
5.13.4 Value addition is another issue. In spite of a large chain of intermediaries the value addition is almost insignificant. The jute bag in which the farmer had packed the potatoes is most likely to reach the retailer and sometimes the buyer, who would spend considerable time in selecting the potatoes while bargaining about the price with the shopkeeper. There would be considerable mark up but virtually no value addition. The worst situation is in the case of vegetables/fruit. Since only about 2% of the fruits/vegetables are processed, there is also very little backward linkages from the processors. However, of late the consumers have started showing their preference for buying processed/semi processed/convenient foods, which is likely to give a boost to backward linkages.

5.13.5 With the implementation of the Horticulture Mission, the production of fruits and vegetables is likely to register substantial increase. The growth of processing industries will be essential to bring better returns to the farmers, particularly, in the matter of the prices of non-tables fruits. The Government may consider encouraging setting up processing zones in rural areas for processing of fruits/vegetables for domestic market on the pattern of processing zones for exports. The possibilities of extending Income-Tax and other benefits/concessions to these units for 5 years on the lines of concessions available for the export oriented units may be considered. The packaging costs of the food processing industry are rather high. It is important to develop cost effective packaging options for the development of the processing of fruits and vegetables.

5.13.6 The fresh fruits and vegetables do have large export potential particularly to the Middle East and Western countries with large Indian population. However, poor infrastructure [storage, transportation, cargo space/rates, facilities at the air/sea ports, etc.] lack of adequate institutional support [credit, market development] and insufficient research efforts are constraints in realizing the potential

5.14.0 Marketing through Pre-Production Agreed Arrangement
5.14.1 In the case of certain vegetable/fruit crops and also specialty crops a new agribusiness model of pre-production agreements between the farmers and corporate houses/processing companies/others are being practiced. These arrangements are being loosely referred to as contract farming though in may of these cases there is no formal
contracts between the farmers and the prospective buyers. Attempts are being increasingly made for building up linkages between ‘farm and the market’. Since the agro-based and food industry requires timely and adequate inputs of the needed quality, several of these business houses have attempted to establish convenient system/models for the purpose. Some of these attempts in certain pockets including contract farming arrangements tried in India are the tomato crop in Punjab [Hindustan liver Ltd & Pepsi] mustard crop in Punjab [Markfed- a cooperative organisation], potatoes [Mc Donalds], wheat in Madhya Pradesh [Rallis & Hindustan Liver Ltd], maize [Venkateshwara Hatcheries Ltd], basmati rice in Punjab, western UP [Pepsi] cotton in Combatore, Tamil Nadu [Appachi Cotton Company (ACC)], Barley in Belgaum, Karnataka [Ugar Sugar Works Ltd] etc.

5.14.2 In several of these cases, there have been gains in productivity after adoption of the above system as the farmers had the benefit of a higher degree of managerial services, technical extension, quality seeds/plants, fertilizers and credit etc. the models have usually been successful in case of crops with niche markets or export potential. It is not clear whether these models would work in case of other crops as well. While it appears almost certain that the productivity could go up initially but problems do start emerging thereafter. In Punjab, where Pepsi & HLL tried these arrangements for tomato, potato and chilli some farmers reported problems like poor technical assistance, delayed payments, manipulations of norms etc by the purchaser. It was reported that some farmers had to wait at the factory gate for a day or so leading to weight loss of tomatoes with the result the firm received more concentrated produce at the same price.

5.14.3 The crucial aspects of these arrangements are those relating to price fixation and dispute resolution. The arrangement which does not fix the price, does not shift the market risk from the producer to the buyer; where the price is specified in the agreement and the prevailing price at the point of marketing is higher, the grower would try to avoid selling under the agreement and would sell in the market. If however, the price is lower, the buyer would try to buy in the open market rather than from the farmers with whom there was the agreement. So, there is an unusual situation, if there is no fixed price, both the grower and the buyer are exposed to market risks and if there is a fixed price in the agreement, there are complications in enforcing it. In a ‘niche’ market or a specialized product the situation is different. In some cases the processor/trader [buyer] might have
already entered into a sale contract or have an export order where the specialized product is needed. Here the market price has no relevance and for both the grower and buyer, it is ‘win-win’ situation to continue working for each other. In the case of other commodities, if the idea is long-term relationship, both the parties may keep temptations to deviate in abeyance. However, such situations where one of the parties is unwilling to honour cannot be ruled out completely. Enforceability of the agreements in the court of law is another issue. It is extremely doubtful whether an individual farmer could take a company to court. For the company also, going to the court against one farmer may not be worthwhile, as the damages awarded may not justify the cost. Under the circumstances, the parties may prefer to have only an understanding with each other. While it is a fact that the purchasers are financially stronger and farmers have weak bargaining strength, often the farmers have local clout to make things difficult for the purchasers. The companies sometimes use a system of reward and punishment to ensure that a long-term relationship develops. Instances of boycotting the entire village [where some farmers ditch the purchaser] or denying certain other benefits to the defaulting farmers and rewarding/honouring them in public functions where they continue supplying produce are not uncommon.

5.14.4 As long as the bargaining power between the two parties is unequal, the models would remain fragile. One way perhaps could be that the producers form groups or cooperatives, which in turn may deal with the purchaser. This would empower the producers and the group/cooperative could become a better guardian of their interests and the arrangements would have better strengths as regard enforceability. Ultimately, these models have to sustain on the momentum of each group’s self interest, each party is closely hooked to each other and if any one link breaks, it is not good for the model as a whole. One has also to remember that the possibilities exist that the purchaser will in due course reduce the prices and other benefits offered to the growers. The important issue is whether the grower is better off as compared to the earlier farming situation or not. If so, this is worthwhile. If the grower is too much worried about the larger share going to the purchaser, it will not help. The attempts however, should be to improve the bargaining power of the producers as mentioned in the earlier paragraph.
5.14.5 It may also be useful to look at the conventional ‘Contract Farming’ model. The contract farming is defined as a system for the production and supply of agricultural/ horticulture produce under forward contracts between producers and buyers. The essence of such an arrangement is the commitment of the producer/seller to provide an agricultural commodity of a certain type at a time and a price and in quality required by a known and committed buyer. The contract farming arrangements could contribute to a) facilitating emergence and growth of processing/trading units b) export of produce from the small farmers c) encouraging high quality production d) enable producers/purchasers to realize economies of scale e) allocation of risks between the producer and the purchaser. While the farmer bears the production related risks, the purchaser bears the market risks f) better credit linkage g) better managerial focus h) better input availability. The contract farming agreements could be broadly classified into three, not mutually exclusive categories: a) market-speciation b) resource providing and c) production management.

5.14.6 There are only limited experiments in contract farming in India excepting in sugarcane cultivation and some niche products, however, the Government have circulated ‘Contract Farming Agreement and its Model Specifications’ among the States. As regards the dispute settlement, the suggestion is to have a body representing the sponsor, farmers and other interested like the Market Committee as the Forum, which could act as arbitrator. The suggestion is that the APMC Act when revised may have an appropriate provision for compulsory registration of all contract farming agreements and the procedure for settlement of disputes arising there from. While providing for a ‘Forum’ for settlement of disputes is desirable, compulsory registration may perhaps not be the most appropriate strategy for contract farming. Another suggestion made is a clause to ensure that the sponsor/purchaser shall not have any right whatsoever over the title or possession of producers land. This is generally welcome to ensure that apprehensions of the producers losing their land are laid to rest.

5.14.7 One also needs to take note of some criticism of contract farming. The first is that the purchaser is quite likely to be interested in short-term gains/profit maximization and may, therefore, suggest practices, which in the long run are not good for the land/other assets of the producer. The purchaser has the option of ‘moving on’ after a few years of
'exploitation' of an area. The second issue relates to possible shifts in favour of export-oriented crops at the cost of crops providing basic food. The third is the preference for the larger producers in choice of partners by the purchaser, ignoring the small landowners. Such practices over a long time could encourage the small farmers to enter into sub-agreements with the larger farmers thereby adding a tier between the grower and buyer or to sell/lease out their land and work as labourers.

5.14.8 It is early to form any clear judgment about contract farming. However, there is no denial that the model offers possibilities of scale economies and also helps in building linkages in the value chain, linking producers directly with the processor/trader. With changing consumption pattern and increasing demand for processed/specialty foods both by local population and exports, these arrangements could multiply in future. The need for the State is to play a proactive role in these developments and not be satisfied by only regulating these developments. **The urgency is to work out a code of conduct for contract farming which is farmer centric to ensure that the interests of the farmers particularly the small farmers are not compromised. Till such a code of conduct is introduced and the farmers are empowered by formation of groups/cooperatives to deal with the buyer on their behalf, one has to be rather cautious about the contract farming system in India.**

5.15.0 Recent Initiatives in Developing Alternate Markets

**ITC’s E-Choupal**

5.15.1 ITC’s E-Choupal provides the farmer an alternate route to the Mandi, without going through the regulated market or the compulsion of selling to the corporate at a predetermined price [under contract farming], as also access to good quality input. It is already covering over 29,000 villages, about 3.1 million farmers through 5,050 Choupals. The ITC has an ambitious plan of covering 10 million farmers and 1 lakh villages with a business turnover of over Rs. 10,000 crore by 2010. The Choupal provides live quotes of not only ITC’s own prices but also prevailing prices in the Mandis across the State. The internet kiosks, [initial capital cost funded by ITC] but operated and managed by a local village person [Sanchalak] also provide information regarding weather, farm practices, risk management, prices of inputs, the price quotes for certain agriculture commodities and an offer to purchase his produce without going through the regulated markets. The
model appears to be an improvement over the contract farming models in as much as the prices are basically determined by the market system of demand and supply. For the ITC, the benefit comes from lower cost of procurement and quality raw material. The ITC also gets a fee from various companies [37 as reported] that sell their products through the e-choupal. These companies display their products on the site, offer special prices and also train the farmers in the usage of their products. The ITC gets a commission on the sales. The Sanchalak gets 5% on all the sales through his kiosk.

5.15.2 In marketing his produce through the e-choupal, the farmer also saves the labour charges, middlemen commission, handling charges and perhaps also in certain unauthorized charges which he may have to pay in the regulated markets. Further, there are no doubts about the weighment [electronic weighing scales are used] and the payment is prompt. The farmers appear to be quite happy with this marketing option now available to them. The ITC purchased 60,000 tons of crop through e-choupal in 2001-02. In 2003-04 it was 2,10,000 tons and in four months of 2004-05, the crop purchased was 1,80,000 tons. Under the arrangements, the farmers could either bring the produce to the ITC warehouse/factory and get reimbursed for the transportation cost, or could hand over at one of the collection centers or Sanchalaks. The crops covered are soybeans, wheat, coffee and shrimp [in Andhra Pradesh under Aqua-e-choupal]. The company has plans to expand into other crops like spices. The company saves on procurement costs and gets the desired quality.

5.15.3 The States covered under the above project either amended the APMC Act or allowed exemptions to enable the ITC to purchase the agricultural produce outside APMC. The experiment has provided the farmer an alternative, a business model for the ITC to shorten the supply chain and a delivery system to the companies to reach the rural areas. It is really a supply chain innovation, which has tremendous potential. It is reasonable to expect other companies to learn, innovate/change as per their requirements and try similar models for reaching the rural areas in future.

5.16.0 The SAFAL System of the NDDB

5.16.1 The National Dairy Development Board [NDDB] has introduced a model for direct sale of vegetables/fruits under SAFAL in Karnataka. Under this system the farmer
associations cover the farmers in a cluster of villages and serve as collection and grading centers. The produce so aggregated and graded is properly packed in plastic trays and supplied at the central auction centre. The Auction Centre operates in a most transparent manner, where premium is on quality. The entire auction system is computerized. In Bangalore, an extremely well laid out market yard with excellent facilities including electronic auction platforms have been developed by the NDDB. The NDDB has also developed a modern retail structure with prices linked to the auction prices, to ensure competition and transparency among retailers. Also in Delhi, there are a very large number of retail outlets for fruits/vegetables etc. under SAFAL model. The APMC Act was amended in SAFAL areas to enable the cooperative sector to take initiative in setting up such producer- oriented markets. The need is however, to develop low cost models for large-scale replication.

5.16.2 These initiatives which in farmers a choice need to be supported and replicated. These could bring competition in agricultural produce marketing and benefit the farmers.

5.17.0 Financial impediments - Negotiable warehouse Receipt system
5.17.1 According to the Report of the Inter-Ministerial Task Force on Agriculture Marketing Reform, micro level studies reveal that the small farm holdings contribute nearly 54% of the marketable surplus and distress sale by these small farmers account for about 50% of the marketable surplus. The farmers do sell their produce to square off their debts soon after harvesting. It is normal for a farmer to get 10-15% discounted price for spot payment for his produce. The solution partly lies in providing them access to safe and scientific storage and an easy farmer friendly pledge/marketing finance system. The total pledge loans given by the banks to the farmers are not much. The commercial banks do not report this as the present MIS does not provide for it, separately and the total pledge loan extended by the cooperatives to their members is negligible though cooperative system provided well over Rs. 25,000 crore as crop loan during, 2002-03. Linking of credit with marketing could improve the quality and quantum of credit flow. The National Bank for Agriculture & Rural Development (NABARD) could play a role in these developments.

5.17.2 While development of rural godowns would help the farmers in storage of their produce and get a better price, an important area for improving marketing [as we have
moved from scarcity to surplus agricultural production] and bringing liquidity in the
system is the encouragement of instrument based or secondary markets by development
of negotiable warehouse receipt system. The banks are presently reluctant to advance
loans against the warehousing receipts of Central Warehousing Corporation (CWC) when
the holder thereof is not the person in whose favour the receipt was originally issued.
Transferability of the warehouse receipt is limited by the fact that the original owner
cannot transfer it to another person without clearing the banks due. While the State
Warehouse Act provide that a warehouse receipt is transferable by endorsement and shall
entitle the holder to receive the goods specified therein on same terms and condition on
which the person who originally deposited the goods, would have been entitled to
receive, due to the above shortcoming the usage of the warehouse receipts as a financial
instrument has not picked up.

5.17.3 The need is to establish a more secure system. If the bankers on the basis of
prescribed norms could accredit the warehouses and the warehouse could provide
certification about the quality and quantity of goods, the receipts would have much more
negotiability. However, this presupposes availability of acceptable grading norms &
standards of the goods kept in the warehouse (which may be acceptable across the
country) and the reliability of the certification system. It is hoped that in due course, with
the development of appropriate legal framework, these receipts could be maintained as
dematerialized securities in the securities depositories and used for settlement etc.

5.17.4 However, the crucial issues are evolving of commercially acceptable quality
standards in respect of different commodities, the accrediting agency working efficiently
to improve confidence, having arrangements for gathering appropriate market
intelligence about pricing and analyzing it for linkage with quality/standards of the
commodities accepted for storage.
5.17.5 The banking system also needs to develop the credit business potential of financing projects for improving/modernization of markets, storage including cold storage facilities, rural based transport operators etc. NABARD could take the lead in assessing the potential and developing model schemes etc. The ICICIs strategy to look at the entire value chain of a product for exposure could help in reducing risks and improve cash flow trappings both of which are important for a banking institution. The public sector banks also need to innovate and bring some aggressiveness in agriculture credit if they want to take this business away from the informal agencies particularly the traders and commission agents. In this context, it may be appropriate to recall the observation of the Advisory Committee on Flow of Credit to Agriculture under the Chairmanship of Shri V.S. Vyas [RBI-2004] on the potential of credit for marketing, ‘In the context of commercialization of agriculture, marketing of agriculture produce has emerged as a challenging area. It requires smooth channels for transport of produce, physical infrastructure such as warehousing, market complex and credit support to producers. The credit needs for the development of market infrastructure for agriculture sector will be enhanced in the context of commercialization and globalization’.

---

**Box-7**

a. To promote development of a national warehousing receipt system for agricultural commodities, as a part of its policy of ensuring that Indian agriculture is globally competitive while enhancing rural welfare and food security.

b. To declare CWC and SWC as Accreditation Agencies for certified warehouses for warehouse receipt.

c. Lay down various standards, specifications for certified warehouses, so also rules and regulations for managing them including fidelity aspects.

d. All licensed warehouses to confirm to the minimum professional standards in order to provide confidence to lenders and public in general. They will be encouraged to develop their own code of conduct for self-regulation.

e. Existing warehousing laws may be suitably amended. A formal regulatory authority may be constituted to enforce standards and protect the interest of those holding warehouse receipt against negligence, malpractices or fraud. The regulatory authority has to be structured to ensure its complete autonomy and freedom form political interferences.

f. To produce latest information system for warehouse receipt to help in identifying ownership of produce, transferors of lien, holder of lien, hypothecation of receipt for loan and trading of the produce in the context of spot delivery.

g. On the negotiability of the instrument i.e., warehouse receipt there may be incidence of various taxes and levies, which should be exempted for five years to begin with, to make these receipts popular.

h. The negotiability of warehouse receipts require amendments to various Acts of Central and State Governments which may have to be looked into.
5.18.0 Commodity Forward Trading

5.18.1 The Forward Market Commission regulates forward trading under the Forward Contracts [Regulation] Act [FCA], 1952 with the main objective of guarding against unhealthy speculation in commodities. Forward or futures trading is done in the recognized exchanges registered under the FCA. There are both single and multi commodity exchanges. While India has a long history of futures markets in agricultural commodities, during the mid sixties to 2002 forward trading was banned for most of the commodities. The situation was reviewed from time to time by experts and the Kushro Committee in early eighties and later the Kabra Committee [1994] recommended reintroduction of futures trading in several agricultural commodities. The Govt. of India have permitted futures trading in many commodities now, including wheat, gram, coarse cereals, kharif pulses, peas, rice, paddy, khandasari sugar, sugar, gur, coffee, potato, turmeric, cotton, raw jute, major edible oils, oilseeds and their cakes, rice barn, chillies, cloves, ginger, rubber, pepper, silk etc. At present 3 national level exchanges and 21 regional exchanges are operating. The experts have estimated potential of futures trading of about Rs. 55 lakh crore annually.

5.18.2 Forward and futures markets enable sellers and buyers to reduce uncertainty and the consequent risk through price discovery ahead of actual production. By aligning their functioning with spot markets, the forward/futures markets can work as a tool to handle complex situations arising from good and bad harvest through stabilizing supplies and prices. The futures market would give signals to the producers to increase/decrease the area under a particular crop. The processors could hedge price risks and avoid storing of goods. An efficient futures market is essential for development of processing industries. The preconditions for the development of futures market are (a) Free commodity market where price is determined by market forces without too much government interference (b) sufficient fluctuations in prices (c) presence of active players in the market (d) large supply and demand of the commodity (e) standardization of produce to be traded (f) proper storage arrangements and a free movement of commodities.
5.18.3 The Inter-Ministerial Task Force on Agriculture Marketing had among others suggested (a) making the Forward Marketing Commission [FMC] an autonomous body like SEBI and (b) amending FMC Act to enable options trading. These suggestion need to be favourably considered. Further the trading procedures could be improved by introducing time stamping obligation and the monitoring of prices by the Exchange officials on a minute–to-minute basis. These prices also need to be disseminated widely with the help of IT. The length of the trading time should also not be very long which adversely affects liquidity and makes close monitoring of the functioning difficult.

5.18.4 A notable recent development has been the establishment of NCDEX [National Commodities and Derivative Exchange] jointly by NABARD, National Stock Exchange, ICICI Bank and LIC. Later, IFFCO, CRISIL, PNB and Canara Bank have also joined it. It is a national level commodity exchange, set up on modern lines on the pattern of NSE where management and ownership is completely different from the trading members. It is now the largest exchange in Asia after Japan and China. Trading is on line through nearly 6000 terminals covering 33 agriculture commodities. Over 430 cities and towns are covered, in December 2004, it reported average daily volume of Rs. 1619 crore and has about 55% share among all commodity exchanges working in India. The NCDEX has over 50 warehouses accredited and more are likely to be accredited. It is learnt that the NCMSL [an off-shoot of NCDEX] is proposing to have 1,000 warehouses across the country by 2007.

5.19.0 Use of information Technology (IT)

5.19.1 IT involves the electronic processing, storing and communication of information. Anything, which could be represented in digital form, is covered by the term information. Use of IT in agriculture marketing is becoming increasingly indispensable. Encouragement needs to be provided to generate and host useful portals, websites database information packages and other software on agriculture marketing. The farmers would increasingly require more and more information about demand, prices, availability of inputs, quality specification, market and transportation charges, arrivals in market, international prices, forecasts of weather, prices and production, rules and regulation at the destination market, legal provision regarding storage, transportation,
labeling, tracing the origin, phyto-sanitary requirements, research findings etc. A subsistence farmer or one who produces low value output for rural periodic market does not need information on these aspects in such details and coverage. High value, market led production would rest on these details. Benefits of off-season and pre-season or end season production, peak demand and high prices period in domestic and international markets would be important details for the crop and variety to be cultivated by modern farmers. Setting up of information kiosks in the markets should be encouraged to enable the farmers to exploit the opportunities being provided by the information revolution.

5.19.2 Agricultural produce marketing requires connectivity between the markets/exporters/growers/traders/industries/consumers through a network with national and international linkages. There is need of such network through which day-to-day commodity arrivals, prevailing rates, export related information could be available.

5.19.3 For penetration of Information Technology at the grass root level i.e., the farmers, the APMC staff, the extension personnel etc. have to be computer literate. Massive programme for computer literacy may have to be undertaken.

5.19.4 An important barrier to realizing the economic benefits of IT is the initial up-front cost of investing in new infrastructure – both hardware and software, the availability of electric power and training. The initial investment cost is coming down and the ITC’s e-choupal business model has shown that the initial cost could be recovered in as short a period as 18 months. While it may not be so in most cases and hence State support may be needed. As regards availability of assured power, battery back ups are partial solution but solar technologies appear to be more promising. Again, ITC’s e-choupal has solar power backup and VSAT connectivity. Training of rural kiosk operators and other field personnel is important and would be an on-going process.

5.19.5 Some of the better known IT initiatives in rural areas are Gyandoot in Dhar district of MP which provided a range of e-governance related information, ITC’s e-choupal, TARA haat operating mainly in Bundelkhand [UP] and in Punjab with a mix of e-governance services and market price information etc. and the NDDB- Karnataka Govt’s SAFAL project which has a completely IT based marketing set up. The above experiments and many other similar initiatives are indicative that there is a potential of
using IT in marketing of agriculture produce or other aspects relating to agriculture and the perceived difficulties of high initial cost, lack of assured supply of electricity or the non-availability of trained manpower etc. can be overcome with imagination and a strong development orientation. The Village Knowledge Centres under the Programme Every Village a Knowledge Centre could impart trade and quality literacy among farm men and women.

5.20.0 Concluding Remarks
5.20.1 The Mid-term Appraisal of the Xth Plan has observed under the Box “The Way Forward” as under
‘Change agriculture marketing laws of the States and facilitate contract farming to help develop the marketing links that are necessary for raising the efficiency of agriculture. Link Central assistance to the initiation of market reforms in order to bring about changes in the Agriculture Produce Marketing Committee (APMC) Acts. However, since transaction costs and contract enforcement can work against small farmers, this must be accompanied by steps to empower the cooperatives/Panchayats to negotiate on behalf of such farmers.’

5.21.0 Summary of Recommendations
5.21.1.0 Legal Issues
5.21.1.1 The State Agriculture Produce Marketing Acts need to be amended to provide for among others, encouraging the private sector or cooperatives to establish markets, develop marketing infrastructure and supporting services, collect charges and allowing marketing without the necessity of going through APMC/licensed traders. Further, the market fee and other charges needs to be rationalized. While the Government of India is attaching considerable importance to amendments of the APMC Act and have also circulated a draft of the amended APMC Act, the response from the some of the States is not adequate. [Para 5.9.5 & 5.9.6]

5.21.1.2 There is an urgent need to undertake a review of the Essential Commodities Act and other legal instruments covering marketing, storing and processing of agriculture produce; some of these Acts and Orders appear to have outlived their utility. [Box-1]
5.21.1.3 The complex tax structure and multiplicity of State level taxes distort the process of trade and marketing. Inter-State and Center-State harmonization of tax law and their administrative system could help in simplification of tax regime which in term would facilitate internal trade. [Box – 3]

5.21.2.0 Markets

5.21.2.1 The coverage of regulated agriculture markets needs improvement. On All India basis, the average coverage of a regulated market is 459 sq. kms. Some of the States where the coverage is below the all India average are: Assam [2257 sq. kms], H.P. [1600 sq. kms], Orissa [1053 sq. kms], Rajasthan [830 sq. kms] and MP including Chattisgarh [719 sq. kms]. The thin spread of regulated markets in areas where road connectivity is also not good makes it difficult for the farmers to reach the market. In the Karnataka Study of 3408 farmers, nearly 22.15% indicated distance as a reason for not selling their produce at the regulated markets. [Para 5.9.1, Para 5.7.1 & Para 5.8.2]

5.21.2.2 There is a need for focused attention on improving the rural periodic markets, which are the first contact point for the farmers. [Para 5.9.1]

5.21.2.3 The infrastructure facilities at most of the regulated markets are inadequate. There is need for considerable improvement particularly for cleaning/grading/drying/storing of the produce, installation of electronic weighing machines, availability of clean drinking water and other amenities for the farmers. [Para 5.9.1]

5.21.3.0 Marketing

5.21.3.1 Auction systems at the regulated markets need to be more transparent so as to avoid any possibility of manipulation of prices by the traders and build the confidence of the farmers. [Para 5.8.1]

5.21.3.2 Professionalisation of the existing regulated markets and restoration of elected boards be given priority. [Box –2]

5.21.3.3 The behaviour/attitude of the Hamals/coolies/weighing men is a source of irritation to the farmers for whom the markets have been developed. Many farmers complain of long delay [necessitating overnight stay] in the markets. [Para 5.8.1]
5.21.3.4 The role of the APMCs/ SAMBs should change from regulatory focus to promotion of grading, branding, packaging and the development of distant and international markets for the local products. [Para 5.9.8]

5.21.3.5 Restructured Land Use Boards supported by a team of experts at the State level should give pro-active advice to the farmers based on meteorological, marketing and managerial information in the matters regarding the choice of crops/varieties/timing etc. Modern high value agriculture would involve greater risks and the farmer would benefit from information based advice rather than scattered information/hearsay/advice by people without strong technical support. [Para 5.10.1]

5.21.3.6 Commodity based farmer’s organizations may be established. These organizations could play an important role in developing market orientation among the farmers and could also articulate farmer’s issues on commodity basis. The DMI in the Agriculture Ministry could take a lead in this matter and facilitate establishment and growth of such farmer’s organizations. [Para 5.10.2]

5.21.3.7 Initiatives, which provide farmer a choice like the ITC’s e-Choupal or NDDB led SAFAL, should be supported and replicated. [Para 5.16.2]

5.21.3.7 Product quality is the key to better prices. Training of farmers in maintenance of quality standards/specification should receive greater attention. The extension agencies/NGOs/PRIs could play a role in this knowledge dissemination. [Para 5.10.1]

5.21.4.0 Post Harvest Operations

5.21.4.1 There is need to improve post harvest operations and handling of produce. The losses in harvesting, threshing, farm storage, packing, transportation from farm to Mandi are quite substantial. These need to be controlled and eliminated. The extension staff/PRIs could play an important role in educating the farmers in better post-harvest practices. There is a need for introducing a post harvest technology wing in every Krishi Vigyan Kendra [KVK]. [Para 5.13.1 & 5.13.2]

5.21.4.2 A strong emphasis on grading is necessary. There is need for fixing quality standards for all agricultural commodities and a need for introducing compulsory grading before sale in the regulated markets in a phased manner. [Para 5.9.2]
5.21.5.0 Supply Chain
5.21.5.1 There are too many intermediaries in the supply chain. Their margins as compared to the value addition provided are unreasonably large. Tightening of the supply chain is called for. The role of the cooperatives in marketing needs to be expanded. To begin with, they could aggregate the produce, improve post harvest handling and provide much needed pledge finance to the farmers. [Para 5.13.3]

(iii) The direct marketing by farmers needs to be encouraged by providing them opportunities for direct sale to consumers in the regulated markets, as also by developing special markets/bazaars for the purpose. [Para 5.13.3]

5.21.6.0 Government Interventions
5.21.6.1 Delay in issue of the Minimum Support Price (MSP) particularly in respect of Kharif crops needs to be avoided. [Para 5.12.6]

5.21.6.2 Implementation of MSP across the regions needs improvement. Except Punjab, Haryana, U.P and Andhra Pradesh to some extent, the prices of agricultural commodities covered under MSP in other States often rule below the MSP in absence of any government intervention. Not withstanding the weaknesses, the MSP may have to be continued in the foreseeable future and its implementation improved. The eastern region needs special attention because of the widespread poverty as also the potential to improve productivity provided the farmers get better prices for their produce. [Para 5.12.5 & 5.12.7]

5.21.6.3 The small and marginal farmers are more concerned about the paid out prices of the purchased inputs. Any decision to reduce subsidies on inputs and allowing compensatory increase in output prices may have to be carefully examined and analysed, as most marginal farmers are net buyer of food grains etc. [Para 5.12.8]

5.21.6.4 The price behaviour of sensitive commodities like milk, potatoes, onions, tomatoes, etc. needs to be closely watched particularly during the glut and off-season for need-based intervention under ‘Market Intervention’ Scheme of the Government of India. [Para 5.12.7]
5.21.6.5 The import tariffs on farm products like oil seeds produced in resource poor particularly dryland areas need to be carefully monitored and maintained at level to provide sufficient incentives to the dryland farmers. [Para 5.12.9]

5.21.6.6 In view of the likely expansion of horticulture production under the Horticulture Mission, the Government may consider promoting processing zones in the rural areas by providing them the Income-Tax and other benefits/concessions on the lines of those available to the Units in the export oriented zones. Further, there is also the need to reduce the high packaging costs and development of cost effective packaging/marketing options. [Para 5.13.5]

5.21.7.0 Financial Aspects
5.21.7.1 There is a need for substantial increase in marketing credit. Credit availability for eliminating distress sales is important. Pledge loans to farmers should be liberalized and encouraged. NABARD could play its promotional and developmental role in improving institutional credit flow for developing infrastructural facilities in the markets. [Para 5.17.1 & 17 5.17.5]

5.21.7.2 There is a need to encourage instrument based or secondary markets of agriculture produce. The constraints in improving the negotiability of the warehouse receipts need to be removed. [Paras 5.17.2 & 5.17.3]

5.21.7.3 Futures trading in commodities is important. It enables sellers and buyers to reduce uncertainty and consequent risks through price discovery and hedging well ahead of actual production. It needs to be encouraged. For better supervision and regulation a SEBI like autonomous body may be created. Option trading also needs to be permitted. [Para 5.18.3]

5.21.8.0 Contract Farming
5.21.8.1 The Government may work out a farmer centric ‘Code of Conduct’ for contract farming arrangements, which should form the basis of all contract farming agreements and also encourage development of farmer’s groups/organisations to negotiate with the purchasers and take care of the interests of the small farmers. Till such time a cautious approach is needed towards contract farming in India. [Para 5.14.8]
5.21.8.2 While prompt settlement of disputes is crucial to Contract Farming arrangements, compulsory registration of Contract Farming agreements with the APMC may not be insisted upon. [Para 5.14.6]

5.21.9.0. Others

5.21.9.1 Indian agriculture must move from low value agriculture to high value agriculture. There is an urgent need to provide extensive training to the farmers and also creation of quality testing laboratories and other infrastructure for the purpose in rural areas. The concept of ‘Farm-Schools’ for lateral training of the farmers needs to be pursued. [Para 5.10.1]

5.21.9.2 The permit system for issue of ‘national permit’ to the transport operators needs to be reviewed. The harassment to which the truck operators are subjected to [insistence on showing the draft paid for obtaining the national permit/or demanding payment at border check posts] need to be curbed. [Box – 3]

5.21.10.0 Use of IT

5.21.10.1 Encouragement needs to be provided to generate and host useful portals, websites, database information packages and other software on agricultural marketing- Organizations including corporates may be supported in their IT based ventures to improve agriculture and agricultural marketing. [Para 5.19.1]

5.21.10.2 Setting up of information kiosks in the markets may be encouraged to enable the farmers to exploit the opportunities being provided by the information revolution. [Para 5.19.1]

Acknowledgement

The National Commission on Farmers acknowledges the cooperation extended by the Department of Agriculture and the State Agricultural Marketing Boards of Madhya Pradesh and Karnataka in organizing consultations with the officers of the Government of India, State Governments, Banks, NGO’s, Industry and farmers on the subject at Bhopal and Bangalore respectively. The sharing of knowledge and experiences by the participants in the above meetings has been of great help in preparation of their note.

Annexure-I
Annexure-I B : Rationale for the recommendations in Annexure-IA

1. In order to increase the gender sensitivity of the Act, it is necessary to clarify that the term ‘his’ wherever it appears in the Act shall include the term ‘her’.

2. (a) The benefit of Employment Guarantee Act should not be restricted only for the poor households but should extend to every household, especially since the Common Minimum Programme also does not speak of Employment Guarantee only for poor households but promises it for rural/urban poor and lower middle class households.

(b) It is felt that an Employment Guarantee for 100 days per household is too low to make a meaningful dent on poverty, especially since both on farm and off farm employment availability and growth continues to be low.

(c) It is considered desirable to provide for a 50 percent reservation for women. It is actually noted that Tenth Plan also provides for a Women Component Plan stipulating at least 30 percent resources allocation for women. However, since minimum wages are being offered under the proposed Act, there is a strong possibility of male members of a household cornering the employment potential available and hence the need for a 50 percent reservation for women, thereby freeing the men to undertake other activities in the rural areas. Empowerment of women and sensitivity to their role of as a housewife and a mother as well as their social and biological constraints etc have to be kept in mind by the Proposed Act.

3. The problems of pregnant and lactating women are sought to be recognized by proposing this clause.

4. If the Central Govt. specifies the wage rate, there is risk of social tension and discord if the Central wage rate and State wage are different. Workers working on a project under the Employment Guarantee Act and those working on state
projects nearby may get paid differently although they would put in the same work and face the same financial and social difficulties. This would be iniquitous. It is best to rely on the State Minimum Wage Act which take into consideration the local income and price levels.

5. There have been examples where the State Govt. have not passed on the benefits under various schemes to eligible beneficiaries inspite of release of funds from the Central Govt. It is, therefore, proposed to spell out the responsibility of the State Govt. towards the eligible households clearly and at the same time protect them if they are made pay the eligible households without release of adequate resources from the Central Govt.

6. While providing for social audit for the works under the Act it is equally important to spell out the responsibility of the Gram Sabha for Gender Audit also in order to protect the interest of women workers specially with regard to provision of amenities for them.

7. It is necessary but not sufficient to focus on works creating physical assets. It is well recognized that investment in human resource development and social sector are equally important and yet these sectors have suffered due to inadequacy of resources. Employment Guarantee Act can be used to provide a major push to activities relating to childcare, health care, sanitation etc. which are important for the quality of life and well being in the rural areas.

Some examples of desirable community service in the rural areas which could provide employment to women and which could be funded through wages under the Employment Guarantee Act are:

1. Sweeping the roads,
2. Collection and disposing of garbage,
3. Clearing the clogged drains,
4. Helping for cattle grazing to reduce school drop outs
5. Helping facilitate 100 percent immunization
6. Helping in cooking and distributing mid day meals
7. Helping in providing ICDS services
8. Helping to look after the young children of working women.

8. It is often being observed that Piece Rate System works to the disadvantage of women and they end up getting less for their efforts. It is necessary to protect women workers through the stipulation that piece rate should not work to the detriment of women.

9. Availability of at least 50 persons for starting a work would perhaps be a too rigid requirement. Depending on local population density, lack of availability of other forms of employment and overall hunger and malnutrition, it should be left to the discretion of the local authorities to start a work even if the number of persons available for work is less than 50. In any case such numbers tend to vary on the basis of seasons/festival etc also.

10. Transparency and responsibility can be achieved only if the records maintained in the Gram Panchayats, in this regard are verified and approved in the Gram Sabha meeting also.

11. Gender sensitivity demands separate hygienic latrines and shade for men and women. Further, a women worker cannot work to her potential unless her child is safe at the worksite, protected by a fenced shelter.

12. One of the major reasons for women not coming forth for work is the existence of infants below 2 years of age. Interests of lactating mother who particularly require food and other financial resources for supplementary nutrition can be protected only if adequate child care is available to them at work site. This may require more than one worker for looking after infants depending on the number of worker on the
work site. The child care workers can be provided orientation training to enable them to look after the children at the work site properly. More importantly norms for nutrition for each child per day must be provided in consultation with child care professionals. Considering that 80 percent of the development of the brain of a child takes place during the first eighteen months of child’s life, the need for employment for its mother and adequate child care and nutrition for the infant at the work site is too obvious to need elaboration.

13. Considering that the public distribution system does in many case provide for foodgrains, it is necessary to increase the proportion of cash in the wages so that other requirements of a poor family, particularly health care and nutrition are adequately taken care of.
Annexure II: Suggestions sent by NCF relating to The Seed Bill, 2004

The non-availability of quality seed in adequate quantity at right time and at the right place has emerged as a serious constraint to enhanced and profitable agricultural production in the country. The various stakeholders - public and private sectors and farmers must coherently address this serious problem. In this context, the need for an effective farmer-centric, unambiguous, functional, unbiased and easily implementable Seeds Act to ensure smooth flow of quality seed from the “breeder” to the farmer in the desired quality, at the right time and at reasonable price can hardly be overemphasized.

The interest of all sectors of the society and needs, aspirations and vulnerabilities of farmers, especially small farmers, must be adequately addressed. In India, this assumes prime importance as the country accounts for 25% of the world’s farmers (115 million farm families against hardly 1 million in OECD countries as a whole). Moreover, 80% of the Indian farmers are small and resources-poor.

The Government of India has formulated a draft Seeds Bill 2004, which is being examined by a Standing Committee of the Parliament before its enactment during 2005. Comments have been invited from concerned corners on the Draft Bill. Seed being one of the foremost issues in the priority areas of the work of the National Commission on Farmers, the Commission offers the following comments on this Bill.

1. Object of the Bill:

The Seeds Bill must be farmer-centric. The objective as stated in the Draft Bill does not reflect the role of this Bill in serving Indian farmers and agriculture. This major omission needs to be rectified. Hence the following formulation is suggested:

“To provide for regulating seeds standards and production, processing, sale, export and import of quality seeds to facilitate timely availability of high quality seeds and planting
material in required quantity to farmers at reasonable price for accelerated agricultural development in the country and for matters connected therewith or incidental thereto.”

2. **Judicious Congruence of the Seeds Bill with other Related Acts:**

The Draft Bill does not seem to be in congruence with the National Agricultural and National Seeds Policy. It is also not harmonized with the Protection of Plant Variety and Farmers’ Right (PPVFR) Act (2001), Biodiversity Act (2002), TRIPS, CBD and FAO Gene Treaty. Some of the important concerned developments, such as the increasing role of farmers in participatory breeding, traditional seed systems operated by a majority small holders, seed villages, seed banks etc have not been internalized in the Draft Bill, and this omission should be corrected. The Harmonization process, however, must not reduce the overall economic and ecological benefit, especially the interests of majority of the small farmers, as sometimes the attainment of uniformity of standards may be dictated by the strict but not so relevant procedures of one or the other sister Act. The proposed Central Seed Committee (Sec. 4 of Draft Bill) should pay special attention to this aspect.

The proposed Seeds Act, along with the other above mentioned Acts or conventions and Treaties, when implemented, is bound to bring significant changes in plant breeding and production and distribution of seed. Their influence on priorities and products, including public goods and improvement of vital ‘orphan’ commodities, seed pricing and availability to small farmers, the realization of Farmers Rights and benefit sharing, especially with the tribals and the grassroot conservers and farmers breeders is yet to be felt and known. Therefore, under the guidance of the Principal Technical Advisor (See item no. 9 below), provisions in some of the Articles of the Seeds Bill, viz. Nos 21, 22 and 46, should be kept in a dynamic phase and should evolve to be more inclusive, equitable and participatory. The enabling mechanisms should likewise be adjusted.

3. **Protection of Farmers’ Traditional Rights on Seed and Strengthening Farmers’**
Seed Systems:

Sections 13(1), 21(1), 22(1), 23(1) and 43, notwithstanding their accent on quality assurance, deny the traditional rights of farmers to sell their home-produced seed in their neighborhood. High seed replacement rate with quality seed in all crops is beneficial to both farmers and national agriculture. But, the fact remains that nearly 75% of the current seed replacement is done by the informal traditional farmer seed system. No seed industry now or in near future can satisfactorily saturate the national seed system in all crops. Moreover, seed industry is generally not interested in supplying quality seed in several ‘orphan’ crops, which do not offer profitable business. Therefore, a law that restricts the farmer seed system can neither be realistic nor truly implementable. The Seeds Bill should therefore proactively promote the informal system of seed production and distribution through enhancing quality literacy and awareness of farmers, improving their skills for quality seed production and retooling the nonformal sector to be as good as the formal seeds sector. The private seed industry generally concentrates on the production and marketing of hybrid (F1) seeds. The Farmers’ Seed System and the Commercial Seed System should become mutually reinforcing.

4. Registration Requirements of Variety:

Compulsory registration of variety for its commercial production, processing, sale and export, as detailed in Section 14, is welcome. It is most desirable to safeguard the interest of farmers and national interest, when devised and implemented to serve these ends. But there are certain ambiguities in the Bill. The Process and consequences of registration of variety under Seeds Bill should in principle be made legally consistent with existing national laws such as the PPVFR Act, 2001; the Biological Diversity Act, 2002 and the Patent (Amendment Act) Act, 2002.

A separate clause may be added in the Bill as 14.4 describing the eligibility criteria for the variety to be registered, which should read as “A new variety should be registered under the Act based on VCU (Value in Cultivation and Use) testing conducted
by the CSC accredited centres. This test should be mandatory for all sectors. The existing All India Coordinated Crop Improvement Project (AICCIP) model, which has played a significant role since its existence in multilocation testing of varieties not only for yield but also for adaptation, reaction to insect pests and diseases, providing farmers with widely as well as locally adapted superior varieties, should be adopted by the CSC for VCU testing. However, to make the system more efficient and transparent, the CSC may like to accredit appropriate centers also from private sector in addition to those from SAUs and ICAR.

Disclosure about the pedigree of the variety / hybrids to be registered should be made mandatory to discourage the unauthorized use of PGR and to enable the benefit sharing.

To harmonize the Seed Bill with PPVFR Act, particularly with respect to Farmers’ Rights, a clause on benefit sharing as per the provision of PPVFR should be added. This would help protection of the interest of the public sector institutions as well as of the farmers. It would be adequate if the Bill contains a provision stating that all the rights of farmers provided for in the PPVFR Act will be safeguarded.

Registration for sale should be acquired only for new varieties as in the Seed Act of 1966 which limits the requirement to notified varieties. No registration should be required for extant varieties and landraces.

To ensure transparency, a process for pre-grant opposition to registration of a seed variety must be included in the Seed Bill, like it is in the PPVFR.

5. **The Seed Bill should not Facilitate Biopiracy by Promoting Unregulated Seed Export**
Although Section 37 on “Export of Seeds” has provisions to regulate and restrict seed trade in the interest of the nation, it should be explicit in context of safeguarding and benefiting from our bioresources. While seed export should certainly be promoted to enhance income and employment, it should be conferred to those varieties which are registered under PPVFR Act, and only to those countries which recognize plant breeders’ rights. Such exports will then be linked to export oriented production with pre-identified export destinations. Export for research should be dealt separately with stringent regulations and liability conditions to exclude abuse of such transfer or on reciprocity basis, as stipulated under the Biodiversity Act.

6. **Labeling on Performance, Compensation and Consumer Protection**

Section 6, 19 and 25 stipulate suitable labeling on the container of seeds intended for sale. Expected Performance of the seed based on specified agronomic performance evaluation is one of these labeling contents. Further, Section 20 says that when a registered seed is sold to farmer, a disclosure should be made to farmer on its expected performance and conditions for realizing such performance. But, this will be possible only when the VAC testing, as mentioned under item 4 above, is made compulsory under the authority of the CSC. The compensation for non performance of seed must be regulated through the National Plant Variety Authority and not through the Consumer Protection Forum or the District Consumer Courts as in the present Draft Bill.

7. **Provision of Registration of Transgenic Variety:**

Section 15 (1) affirms requirement to obtain clearance under Environment (Protection) Act to receive registration for a transgenic variety. However, a provision is added for granting provisional registration for a period not exceeding two year for transgenic varieties. This implies that a transgenic variety can secure a provisional registration for seed production and sale before it is officially recommended for general cultivation on the basis on biosafety and environment evaluation by the competent authority under the EPA. This provision on all counts is against public interest and violates
the EPA regulations. The damage done to the environment by the commercialization of the transgenic variety (if any) during the period of provisional registration cannot be undone if later denial of clearance by the EPA comes. The procedures for the release of GM (genetically modified) varieties, already in force, should be strictly followed.

8. **Offences and Punishment:**

   The small token penalties for violations contained in the Seed Bill must be revised. When the declared source of registered material has been accessed illegally, registration would be cancelled and criminal and civil liability will be determined.

9. **Management of the National Seed System**

   Necessary institutional and financial supports should be provided to establish and operate a world-class enabling mechanism to capture the various national and international opportunities consistent with the national agricultural goal. While the Chair (Secretary DOA) of the Central Seed Committee, in consort with the Provincial Seed Committees, will ensure implementation of the programme, an eminent expert in this highly specialized area should be the Principal Technical Advisor, with a tenure of at least five years, who should be responsible for harmonization and coordination between Central and State Governments and among States in all technical matters. A national grid of well-equipped seed testing laboratories operated by highly skilled human resources should be established. Seed, gene and quality literacy should be promoted at all levels, from farmers to policy makers, by organizing training programmes.

10. **Conformity with existing Acts and Procedures**

    The Seeds Bill should not try to undermine the farmer/primary conserver friendly provisions of the PPVFR and Biodiversity Acts. It should not also undermine the existing procedures for the assessment and release of genetically modified crop varieties. Its main
aim should be to strengthen the integrated growth of farmers and commercial seed systems, so that every farm woman and man has access to high quality seed/planting material at the right time and place and at appropriate prices.

In order to adequately address farmers’ concerns, the membership of the Central Seeds Committee (CSC) may be enhanced from seven to twelve which should include at least five farmers/farmers’ representatives. Representation of women farmers, horticulturalists and farmers from disadvantaged areas should be ensured in the Committee to enhance the inclusiveness.
Annexure III : Suggestions made by NCF relating to: Agriculture Credit - Some Issues

The Chairman, National Commission on Farmers along with the members met the Hon’ble Union Minister for Agriculture and Food on 6th April, 2005. The Secretary, Agriculture & Cooperation, Secretary, Food & Public Distribution, Secretary, Animal Husbandry & Dairying, Secretary Department of Women & Child Development, Govt. of India and other senior officers from different departments were present. During the discussions, the Union Minister indicated that while the flow of agricultural credit during 2004 - 05 was likely to reach about Rs.1.08 lakh crore, showing nearly 30% increase over the 2003-04 level, some issues including the rate of interest charged by the Cooperative Banks and the arrangements for providing relief to the farmers in the case of damage to the crops due to natural calamities were causing concern. He desired to have a note covering the above aspects. These issues are discussed in the following paragraphs.

2. With a view to providing the benefit of declining interest rates to agriculture and particularly to the small farmers, the Indian Bank Association had advised the public sector banks in 2003 to reduce their lending rate to not more than 9 percent per annum on crop loans up to a ceiling of Rs.50,000. While the Commercial Banks have by and large, been providing loans to the farmers at low rate of interests, the Cooperative Banks are finding it difficult.

3. The rate of interest charged to the ultimate borrower by the cooperative system in general is in the range of about 11 to 12% per annum. However, in some States like Andhra Pradesh, Karnataka etc. where the State Government is subsidizing cooperative banks, the rate charged to the final borrower is even lower than the rate of interest charged by the Commercial Banks. In other States, where such subsidies are not available, the rate of interest charged by the Primary Agriculture Credit Societies (PACS)
to their members is higher than that charged by the Commercial Banks for agricultural loans.

4. This is mainly due to higher costs of funds and the cumulative impact of the margins retained by the different tiers in the cooperative credit system. One has to remember that the co-operative credit system reaches the ultimate borrowers (nearly 12 crore members of which about 50% are borrowing members*) through 1,12,309 PACS located at the village level, while the Scheduled Commercial Banks had about 32,640 rural branches (as on 31.03.2001) with a total of only 1.96 crore rural borrowing accounts. The reach of the cooperatives is much deeper and it also has a larger network, which enables it to deliver financial services to the members nearly at the doorsteps thus, reducing the borrower’s transaction cost, which he would incur if he were to approach the branch of a commercial bank or the RRB. However, this adds to the transaction cost of the cooperative credit delivery system. As regards the cost of funds, on a macro basis the working funds of the cooperatives consist of deposits (about 80%) and refinance (about 20%**). The cooperative banks offer a higher interest to the depositors and the bulk of their deposits are term deposits, which attract higher interest. The slight concessionality available to them on NABARD refinance is not enough to provide them adequate leverage to dispense credit to the ultimate borrower at the rate of interest comparable to the commercial banks. It may be recalled that earlier, refinance from (NABARD/RBI) used to form over 50% of the total working funds of the cooperative banks and the interest charged by RBI on this line of credit was 3% below the Bank Rate, which provided better leverage to the cooperative banks to lend at lower rate of interest.

5. The interest rate on loans would primarily depend on (a) the cost of funds, (b) transaction cost and (c) risk cost. With the southward trend of the interest rate, the cost of

---

* Report of the Task Force under the Chairmanship of Prof. A. Vaidyanathan  
** The Advisory Committee on the flow of credit to Agriculture under Chairmanship of Prof. V. S. Vyas
funds of Commercial Banks has declined. At present the rate of interest on term deposits is in the range of 5 to 6 percent or so while saving deposit rate is 3.5 percent p.a. On the other hand, as stated earlier, the Cooperative Banks have been offering a slightly higher rate of interest to their depositors and bulk of their deposits are in the nature of term deposits. The impact of the declining interest rate has therefore been less in the case of Cooperative Banks, than in the case of Commercial Banks. It is only when the fixed deposits accepted at the higher rate of interest mature, the benefit of low interest rates would have full impact on the overall cost of their funds. Over time, the cost of funds of the Cooperative Banks would decline but it would take comparatively longer time to register the full impact of the downward trend in interest rate.

6. The transaction cost of the banks includes the establishment cost and the cost of management/manpower. There is a need for all banks to keep the transaction cost to the bare minimum by use of IT, innovations in operations and reduction in expenditure on establishment/manpower etc. Further, as the volumes increase the transaction cost tends to come down. While there is scope for the Cooperative Banks to reduce the transaction cost and work more efficiently, the paucity of resources is a constraint in greater use of IT, ATMs and other innovative systems, etc.

7. As stated earlier, the increase in volume reduces the transaction cost of per unit of money lent. While in the case of Commercial Banks, their direct agriculture loans form only around 11 percent of the net bank credit, in the case of Cooperative Banks the percentage may be as high as 60 to 70 percent in some cases. The direct agriculture loans are smaller in size and hence the transaction cost per unit of money lent is higher. While the Commercial Banks have considerable scope of cross subsidization because of a very diverse portfolio, such cross subsidization is extremely limited in the case of the Cooperative Banks.

8. The risk cost is another important component of the total cost of operations of banks. The risk cost emanates from a host of factors including failure of investments, inadequate
returns due to weather/market risks, defaults due to improper appraisal of loans, diversions of loans, poor follow up and inability to realize the securities available to the bank. If the credit risks caused by climatic factors, price fluctuations, poor health/death of the borrower could be covered by appropriate financial instruments (insurance, futures etc), the total risk for the lending institution would be reduced and interest rate on loans could decline. In absence of availability/use of the financial products covering these risks, the banks have to add a component of risk cost based on their past experience and perceptions.

9. The Report of the Advisory Committee on Flow of Credit to Agriculture, under the chairmanship of Prof. V.S. Vyas (2004) had examined the question of reduction in the interest rate on agricultural loans by banks. The Report has provided some details of cost/margins and the impact of reduction in interest rate on agriculture loans by 2% on macro basis by the Commercial Banks and the Cooperative Banks. The details based on the aggregate position of the commercial banks for 2002-03 was as under

*(Assuming 50% of the total outstanding were direct agriculture advances)*

11. It would be seen that the commercial bank's margin was to go down slightly with the reduction of interest rate due to reduction in interest rate on agriculture loans by 2% but in the case of the cooperatives (DCCBs) the reduction would lead to a substantial negative net margin.

12. Interestingly, the transaction cost plus risk cost in the case of both the commercial banks and the cooperative banks was nearly the same (3.61 in the case of commercial banks and 3.60 in the case of cooperative banks). The risk cost at DCCB level at 1.36% was low but it needs to be remembered that the DCCB's do not lend directly to the individual farmers but the credit is routed through the PACS etc, which primarily absorb the credit risk of lending to the ultimate borrower.
13. Presently, the interest rate charged by the DCCBs to the PACS in some of the States is not more than 9% p.a., which is charged by the commercial banks to their clients. However, PACS add about 2 to 2.5 percentage points as their margin, which increases the interest rate, which the ultimate user of credit pays. The PACS have an important role in the cooperative credit system. As a matter of fact, this is the level, which needs maximum attention and support but rarely gets it. Improvement in the financial health of the cooperative credit delivery system on a sustainable basis would be possible only if the PACS were to become more efficient, transparent and financially stronger.

14. While there is a need to improve the efficiency of the cooperative credit system and all efforts need be made to encourage minimizing overhead costs, cost effective usage of IT etc, the items, which offer greater scope of cost reduction are the prevailing high cost of funds and the risk costs. The Advisory Committee on Flow of Credit to Agriculture (Prof. V.S. Vyas Committee) has observed, "considering the fact that old high cost deposits will be retired in a couple of years there appears to be the possibility of the cost of funds going down by 0.5% to 1% across the banks. The decline would be more pronounced in the case of DCCBs and the RRBs, given their large share of high cost deposits." These banks, particularly the cooperatives also need to improve their 'Funds Management' to reduce the cost and improve their earnings. The important issues are whether for a short to medium term period there could be a special dispensation to improve the proportion of NABARD refinance in the total funds of the cooperatives [according to V. S. Vyas Committee, the ratio is 1:4 on a macro basis] and also a reduction in the interest rate charged on the refinance amount. As stated earlier, at one time, the RBI refinance to cooperative banks for crop loans used to be at 3% below the Bank Rate and the proportion of RBI refinance and deposits in the working funds of the cooperatives was about 1:1. While it may not be possible to go back fully to the earlier dispensation for all times, but it could it be tried as a carefully worked out scheme to provide relief particularly to the small/marginal and the dryland farmers who are facing considerable financial stress. This could help.
15. As stated earlier, the matters concerning credit risks in agriculture financing are important and these impact the rate of interest. The present level of recoveries and the prevailing credit discipline under the cooperative credit system are not sustainable. The recoveries at the PACS level have to be much higher. A small-localized institution working at the village level, which has complete information about the investment, state of the crop, credit history of borrowers etc. should have 'no tolerance' to willful defaults. There is a need for considerable improvement in the recovery system, the environment and also introduction of a system of incentive to encourage on time payment.

16. Then, there are the sectoral risks both at the individual level as well as the systemic risks. Efforts to reduce individual risk (by selling stored produce, taking up a group of economic activities etc.) and dissemination of information regarding improved technologies and practices to reduce production risks have to be continued as an on going process. The systemic risks i.e. common to a large group of farmers could be minimized by an effective crop insurance system. Though the recent efforts to introduce new products and to improve the crop insurance schemes are praiseworthy, the system of settlements/verification and delays etc. cause certain amount of resentment and uncertainty in the minds of individual farmer. An insurance cover should fully assure the insured that if a particular event takes place he/she would be compensated for the loss. The present crop insurance does not provide such assurance to the insured farmer/the financing bank. This impacts the credit flow and perception of risk both from the viewpoint of the farmer and the banker. Any improvement in mitigation of crop risks due to climatic factors would help in overall reduction in the interest rates.

17. While interest rate is an important aspect of credit, timeliness and adequacy of credit are also equally important. The ultimate borrower is concerned about the total expenses involved in getting a loan and servicing it. A paper of Anita Gill published in Economic & Political weekly [14-20 August, 2004] based on experience of certain districts of
Punjab observes "Then there are additional costs involved like frequent visits to the institution, fee, submission of documents (which more often than not require payment for services to someone who can fill the forms of the illiterate farmers) etc. All expenses can be added up in the rate of interest and the institutional rate of interest then is almost at par with the informal rate of interest".

18. A rural financial access survey (RFAS 2003) conducted by the World Bank and NCAER in UP and AP has also pointed out about considerable time gap in sanction of loans and substantial expenditure which the small borrower incurs in availing institutional credit in rural areas.

19. It is important that all aspects of the delivery system are looked at closely and improved so that credit to the farmers is adequate, timely, hassle free flexible and at reasonable costs.

**Provision of Relief to the Farmers in case of Natural Calamities**

20. As regards the relief to the farmers in case of loss of crop due to flood/drought etc., farmers in the areas covered by the crop insurance are much better placed. Restructuring/conversion of short-term crop production loans into term loan provides temporary relief to the farmers. The ability of the cooperative banks to provide this temporary relief largely depends on the financial support of NABARD. In the case of the commercial banks which have all India coverage, the flood/drought etc. are likely to impact only a small percentage of their direct agriculture loans as these natural disasters are likely to be localized. Further, since direct agriculture loans form only a small part [around 11 %] of their total loan outstanding, these banks can take care of such restructuring/ conversion from their own funds and the impact on their funds flow/liquidity is very marginal. However, the position of the localized DCCBs in this regard is different. Many of the DCCBs have 60 to 70% of their total outstanding loans for crop loans and a drought/flood in the district could impact most of their crop loan portfolio. If these banks were to provide moratorium on interest/principal and convert these loans into term loans,
their income flow and liquidity would be seriously impaired unless these banks were to get similar relief from NABARD. For obvious reasons, NABARD insists on declaration of 'annawari' and State Government guarantee before it extends conversion facilities to the banks. These are cumbersome and take a time. As a result, conversion of loans gets delayed and the farmer becomes defaulter and ineligible for fresh finance. Another issue is that the total balance under the National Rural Credit Stabilization Fund with NABARD [which is used for converting short-term loans into term loans] as on 31.03.2004 was only about Rs.1104 crore. This need to be strengthened to enable NABARD to have adequate resources for meeting a situation where large part of the country were to be affected by droughts/floods etc in successive years. NABARD on its part has also to look into its procedures/systems/instructions etc to make them more user friendly and to ensure that the conversion facilities are extended expeditiously.

21. While conversion/restructuring provides temporary relief to the farmers [by way of postponement of repayment obligation], it is also necessary to have a long-term remedy to take care of the impairment of the repaying capacity of the farmers due to successive calamities like floods/droughts etc. The V.S. Vyas Committee [referred to earlier] has recommended setting up of an 'Agri Risk Fund' with equal contribution from the Central and State Governments and the banks. Such a 'Fund’ could help in mitigating risks of the lending banks and the hardships of the farmers. The suggestion needs consideration.
ACKNOWLEDGMENT

National Commission on Farmers acknowledges the valuable technical contributions of Ms. R.V. Bhavani, OSD to Chairman, NCF and Research Officers: Dr (Ms.) Laxmi Joshi, Dr. Deepak Rathi, Dr Pavan Kumar Singh and Dr Ramesh Singh and the sincere work of the secretarial staff of the Commission for the preparation of the Second Report.

TERMS OF REFERENCE
FOR
NATIONAL COMMISSION ON FARMERS

- Work out a comprehensive medium-term strategy for food and nutrition security in the country in order to move towards the goal of universal food security over time.

- Propose methods of enhancing the productivity, profitability, stability and sustainability of the major farming systems of the country based on an agro-ecological and agro-climatic approach and the harnessing of frontier technologies.

- Bring about synergy between technology and public policy and recommend measures for enhancing income and employment potential in rural areas through diversification, application of appropriate technology including IT for information on market, weather, credit facilities and e-commerce, training and market reforms.

- Suggest measures to attract and retain educated youth in farming and recommend for this purpose; methods of technological upgrading of crop husbandry, horticulture, animal husbandry, fisheries (inland and marine), agro-forestry and agro-processing and associated marketing infrastructure.

- Suggest comprehensive policy reforms designed to enhance investment in agri-research, substantially increase flow of rural credit to farmers including small and marginal, triggering agricultural growth led economic progress, which can lead to opportunities for a healthy and productive life to rural families.

- Formulate special programmes for dryland farming for farmers in the arid and semi-arid regions, as well as for farmers in hilly and coastal areas in order to link the livelihood security of the farming communities living in such areas with the ecological security of such regions. Review in this context, all ongoing Technology Missions like those relating to pulses, oilseeds, maize, cotton, watershed etc. and recommend methods of promoting horizontal integration of
vertically structured programmes. Also suggest credit-linked insurance schemes which can protect resource poor farm families from unbearable risks. Further, suggest methods of strengthening and streamlining the National Horticulture Development Board.

- Suggest measures for enhancing the quality and cost competitiveness of farm commodities so as to make them globally competitive through providing necessary facilities and application of frontier science and promote quality literacy for codex alimentarius standard, sanitary and phyto-sanitary measures among farmers through reorienting and retooling extension machinery. Also suggest methods of providing adequate protection to farmers from imports when international prices fall sharply.

- Recommend measures for the credit, knowledge, skill, technological and marketing empowerment of women, taking into consideration the increasing feminization of agriculture and the proposed conferment of right to land ownership.

- Suggest methods of empowering male and female members of elected local bodies to discharge effectively their role in conserving and improving the ecological foundations for sustainable agriculture like land, water, agro-biodiversity and the atmosphere with priority attention to irrigation water.

- Consider any other issue, which is relevant to the above or is specially referred to the Commission by Government.

The Commission is to submit a medium term policy for food and nutrition security in the country in order to move towards the goal of universal food security over time within the next three months and to submit its recommendations on other Terms of Reference as soon as practicable and in any case on or before 13\textsuperscript{th} October, 2006. The Commission, however is permitted to submit interim reports on any of the Terms of Reference it deemed fit or expected of it.

[Ministry of Agriculture Resolution No.8-2/2003-Policy(ES) dated 18\textsuperscript{th} November, 2004]
COMPOSITION OF THE
NATIONAL COMMISSION ON FARMERS

The composition of the reconstituted National Commission on Farmers is as under:

Chairman
Prof. M.S. Swaminathan

Full-time Members
Dr. Ram Badan Singh
Shri Y.C. Nanda

Part-time Members
Dr. R.L. Pitale
Shri Jagdish Pradhan
Ms. Chanda Nimbkar
Shri Atul Kumar Anjan

Member Secretary
Shri Atul Sinha

[Ministry of Agriculture Resolution No.8-2/2003-Policy (ES) dated 18th November, 2004]
1. 1968 marked the beginning of the green revolution leading to quantum jumps in the productivity and production of wheat and rice. The last 10 years have witnessed a fatigue in the green revolution with the growth rate in foodgrain production falling below population growth. Thus, human numbers are increasing faster than our capacity to make the goal of food for all a reality. At the same time, consumption is not going up due to inadequate purchasing power at the household level. A famine of jobs/livelihoods as a result of poor growth of opportunities for employment in the rural non-farm and off-farm sectors is leading to a famine of food at the household level. According to the Union Planning Commission, we are off-track in achieving the UN Millennium Development Goal of reducing the number of hungry persons by half by 2015. Also, we are off-track in reducing infant and maternal mortality rates and in achieving universal primary education.

2. Our Prime Minister has rightly emphasized the need to double annual foodgrain production from the present 210 million tonnes to 420 million tonnes within the next 10 years, i.e. by 2015, which is also a benchmark year for achieving the UN MDGs. This will call for producing at least 160 million tonnes of rice from 40 million ha and 100 million tonnes of wheat from 25 million ha. Pulses, oil seeds, maize and millets will have to contribute 160 million tonnes. In addition, the national goal is to raise the production of vegetables and fruits to over 300 million tonnes by 2015. Since land is a shrinking resource for agriculture, the pathway for achieving these goals has to be higher productivity per units of arable land and irrigation water. Factor productivity will have to be doubled, if the cost of production is to be reasonable and the prices of our farm products are to be globally competitive. The average farm size is going down and nearly 80% of the farm families belong to the marginal and small farmer categories. Fortunately, the ownership of livestock is more egalitarian. Enhancing small farm productivity, and increasing small farm income through crop-livestock integrated production systems
and multiple livelihood opportunities through agro-processing and biomass utilization, are essential both to meet food production targets and for reducing hunger, poverty and rural unemployment. Programmes designed to achieve these goals must be engendered, since there is increasing feminisation of agriculture, poverty and under-nutrition, as well as unfortunately HIV/AIDS.

3. 2005 has been a difficult year both for the nation and for farm and fisher families. Beginning with the titanic tsunami of 26 December 2004, and ending with the disastrous earthquake in Kashmir and floods in Tamil Nadu, our farm and fisher families have been subjected to the fury of nature in the form of drought, unseasonal and heavy rains (like the one which caused damage to the onion crop in Maharashtra) and floods. Institutional support to small farmers is weak. The same is true of post-harvest infrastructure. For example, even now paddy is being spread on the roads for drying in many places. The spoilage losses can be as high as 30% in the case of vegetables and fruits. Institutions, which are supposed to help farmers, such as research, extension, credit and input supply agencies, are by and large not pro-poor and pro-women. Mechanisms for risk mitigation are poor or absent. Hardly 10% of farmers are covered by crop insurance. Farm families are also not covered by health insurance. There is no Agricultural Risk Fund. Both risk mitigation and price stabilization are receiving inadequate policy support. The cost of production is invariably higher than the minimum support price, due to ever-increasing prices of diesel and other inputs. Investment in agriculture has suffered a decline over the past two decades. Capital formation in agriculture and allied sectors in relation to GDP started declining in the 1980s and is only now being reversed. This has adversely affected irrigation and rural infrastructure development. An unfortunate consequence of the constellation of hardships faced by small farm families is the growing number of suicides among farmers. The situation is particularly alarming in parts of Vidharba of Maharashtra State. To our shame, the suicide hotspots include Wardha district, where Mahatma Gandhi spent a significant part of his life, fighting for freedom from colonial rule, so that the country can be rid of hunger, poverty and gender injustice.
4. The cost-risk-return structure of farming is becoming adverse. Consequently, indebtedness is growing in rural areas. In Maharashtra over 55% of the State’s farm households are in debt. Average household size of farmers is 5.5 at the All-India level. In the low-income groups, the average size goes up to 6.9. According to NSSO-59th round, the average monthly per capita consumption expenditure of farm households across India was Rs. 503 in 2003. Endemic hunger (i.e., chronic undernutrition), is high both in families without assets like land or livestock, as well as in families with small land holdings without access to irrigation. Policy reform in agriculture is thus overdue. Such policy reform should be pro-small farmer and pro-women and pro-landless agricultural labour. If we do not attend to the problems of small farm and landless agricultural labour families with a sense of urgency and commitment, the “Indian Enigma” of the co-existence of enormous technological capability and entrepreneurship on the one hand, and extensive under-nutrition, poverty and deprivation, on the other, will not only persist, but will lead to social disruption and violence and increasing human insecurity. Without peace and security, enduring economic progress will not be possible. NCF therefore recommends that the agricultural year 2006-07 be designated as the Year of Agricultural Renewal.

5. During this year, an integrated package of measures should be introduced in every part of the country to increase farm productivity and profitability in perpetuity without associated ecological harm. The programmes should cover all our major agro-ecological regions-arid, semi-arid (i.e. dry-farming) hill, coastal and wet (i.e. irrigated or high rainfall) zones. The present agricultural crisis can then be converted into an opportunity for not only reversing the decline, but for taking the agricultural revolution forward by helping farm families to bridge the gap between potential and actual yields in all major farming systems through mutually reinforcing packages of technology, services and public policies. The programmes initiated during the 2006-07: Year of Agricultural Renewal by Central and State Governments, Panchayati Raj institutions, Agricultural, Veterinary, Rural and Women’s Universities and IITs, Private and Public Sector Industries, Civil Society Organisations and Mass Media should be designed to foster productivity, quality, sustainability, profitability and employment revolutions in the farm
sector in all the over 600,000 villages in the country. It should help to promote job-led economic growth in our villages.

6. The following should be the major components of the Action Plan for the Year of Agricultural Renewal. All of them require concurrent and integrated attention.

6.1.1 **Soil Health Enhancement:** Agricultural Universities, ICAR and CSIR Institutes, Krishi Vigyan Kendras, Fertilizer Companies, State Departments of Agriculture and Farmers’ Associations and Panchayati Raj institutions should commemorate 2006-07 as the Year of Soil Health Enhancement. The International Crops Research Institute for the Semi-Arid Tropics (ICRISAT) located at Hyderabad may be actively associated in this programme. ICRISAT has very valuable information on the soil health status in dry-farming areas, ICRISAT, CRIDA, CAZRI at Jodhpur and the National Bureau of Soil Survey and Land Use Planning of ICAR can provide technical support and assist in monitoring. For this purpose, the following steps need to be taken:

i. Re-tool and re-equip all Soil Testing Laboratories in order to enable them to provide each farm household with a **Soil Health Card**, which contains integrated information on the physics (soil structure, occurrence of hard pan in the subsoil, etc.), chemistry (soil organic matter and macro- and micro-nutrient status), and microbiology (occurrence of earthworms, soil micro-organisms etc.,) of the soils. The Soil Health Cards should stimulate balanced fertilization, including the amelioration of micro-nutrient deficiencies.

ii. Promote through campaigns and demonstrations, the introduction of fodder/ grain legumes in the crop rotations as also the cultivation of green and green-leaf manure crops.

iii. Composting of all agricultural residues and wastes and the use of microbial fertilizers and farmyard manure should be promoted to the maximum extent possible.

iv. Methods of improving soil health through integrated nutrient supply will have to be prescribed and farmers should be assisted to adopt the recommendations.
v. All staff working in Soil Testing Laboratories should be retrained.
vi. Integrated wasteland and biofuels programme should be promoted.

vii. The Agri-clinics programme should be restructured and revitalized and farm graduates should be encouraged to take to a career of self-employment in the rural services sector.

viii. Breeding soils for higher productivity may be undertaken in the case of problem soils and wastelands.

ix. Wasteland development could be linked to the production of biofuel and industrial raw material (for the production of paper and board, rayon, packaging material etc) as well as fodder, firewood etc.

tax. Community Land Care movements may be launched by Panchayats

6.1.2 Soil Health Enhancement holds the key to improving the return from investment in other inputs like seeds and water. Dry-farming areas need particular attention from the point of view of overcoming micro-and macro-nutrient deficiencies. As stressed by the Prime Minister, the second green revolution has to begin in dry-farming areas

6.2.   **Irrigation Water: Supply Augmentation and Demand Management:** Water is a public good and a social resource and not private property. The privatization of water supply distribution is fraught with dangers and could lead to water wars in local communities. **Increasing supply through rainwater harvesting and recharge of the aquifer should become mandatory.** In addition, a nationally debated and accepted strategy for bringing 10 million hectares of new area under irrigation under the Bharat Nirman programme should be developed. The Polavaram Project to be built across the Godavari in Andhra Pradesh is a case in point. Different viewpoints can be reconciled only by dialogue and consensus building. All existing wells and ponds should be renovated. Demand Management through improved irrigation practices, including sprinkler and drip irrigation, should receive priority attention. A Water Literacy movement should be launched and regulations should be developed for the sustainable use of ground water. Seawater farming should be promoted in coastal areas through the cultivation of mangroves, salicornia, casuarina and appropriate halophytic plants. The
conjunctive use of rain, river, ground, sea, and treated sewage water should become the principal method for the effective use of available water resources. In water scarce areas, the land use system should place emphasis on the cultivation of high value – low water requiring crops, such as pulses and oilseeds. Pulses and oilseed villages can be promoted where all farmers work together in harvesting rainwater and sharing the water equitably for growing pulses and oilseeds. Promotion of “Hybrid arhar (pigeon pea) villages” can be the starting point of a pulses revolution. In paddy and sugarcane, water saving methods of cultivation like those inherent in the “System of Rice Intensification” (SRI) methodology should be perfected and popularized. More crops per drop of water should not remain just a slogan. Land use decisions are also water use decisions. Hence, the choice of cropping systems should be based on irrigation water availability including rainfall pattern. Watershed management should be linked to the different Technology Missions as emphasized in our earlier reports, so that the concurrent availability of water and of the other inputs like seeds needed to optimize the benefit from irrigation water can be ensured. Low cost green houses can be promoted in areas where evaporation exceeds precipitation during many months in a year. Panchayats may be assisted in launching water literacy and water quality management programmes.

6.3. **Credit and Insurance:** Credit reform should consist of the following measures:

i. **Interest rate on agricultural loans:** The spread between the deposit and lending interest rates in India is high by international standards. The need is to improve the efficiency in the financial intermediation by controlling both the transaction cost and the risk cost. On the part of the Government, crop insurance as well as the speed and manner in which the debt recovery and settlement process operates would need to be considerably improved. These improvements could be brought about in the medium to long term. A high interest rate means that a greater proportion of income has to be diverted to interest payment. Keeping in view the decline in the profitability of agriculture, and increasing farmers’ distress and indebtedness, the government may consider providing support to the banking system for reducing the rate of interest for crop loans to 4% during the Year of Agricultural Renewal.
ii. **Compounding of interest on arrears:** The compounding of interest on arrears may be applied only in the case of recalcitrant borrowers who do not pay the dues inspite of having adequate repaying capacity. The farmers facing erosion in income and consequently their repaying capacity due to market failure should not be charged compound interest on arrears.

iii. **Shift from micro finance to livelihood finance:** There is an urgent need for a paradigm shift from micro-finance to livelihood finance, as the access of the poor to micro-finance alone is not likely to alleviate their poverty. Livelihood finance is a comprehensive approach to promoting sustainable livelihoods for the poor, which includes financial services, [including insurance for life, health, crops and livestock: infrastructure finance for roads, power, market, telecom etc and investment in human development], agriculture and business development services [including productivity enhancement, local value addition, alternate market linkages etc] and institutional development services [forming and strengthening various producers’ organisations, such as SHGs, water user associations, forest protection committees, credit & commodity cooperatives, empowering Panchayats through capacity building and knowledge centres etc.].

iv. **Access to institutional credit in poverty stricken tribal areas:** Special efforts are required to improve the access to institutional credit in the poverty stricken tribal areas in the dry land agriculture regions like the Kalahandi belt of Orissa/ Palamau region of Jharkhand/ tribal areas of Chattisgarh/ Madhya Pradesh/ Andhra Pradesh and the Vidharba region of Maharashtra.

v. **Agri-risk Fund:** There are areas in our country, which have recurrent and frequent drought/floods etc, which cripple the incomes of the farmers. These farmers become defaulters to the banks and thereby become “push-outs” of the credit system. Rescheduling and restructuring of their loans are not enough in the event of successive natural calamities. The government of India may step in to create an Agriculture-Risk Fund to provide relief [waiver in full:/ part of loan and interest] to the farmers in the case of successive droughts, etc. and also waiver of interest on loans in areas hit by droughts, floods, heavy pest infestation etc. This
Fund should have contributions from the Central Government, State Governments and Banks in a predetermined fashion.

vi. **Distress ‘hot spots’ – moratorium on debt recovery:** There is a need for moratorium on debt recovery including loans from non-institutional sources in distress hotspots, till reasonable profit margins in agriculture operations are restored. The debt recovery may be staggered in easy installments. For this purpose, liquidity support may have to be provided to the localised banks like the RRBs/Cooperative Banks etc.

vii. **Credit for low cost/sustainable agriculture:** There is need for developing suitable project profiles for low input sustainable agriculture and aquaculture. Institutional credit should also be available for viable projects of sustainable farming practices including the upkeep of traditional breeds of cattle.

viii. **Issue of Kisan Credit Card to women farmers:** The Kisan Credit Card (KCC) is a major innovation in agricultural credit. However, inspite of nearly 4.5 crore KCCs issued by the banks, very few cards have been issued to women farmers. As a matter of fact, no separate data are available in this regard. Keeping in view the fact that there are a very large number of women-headed farming families, particularly in the hills and NE Region, special effort is needed to issue KCC to these farmers. The banks may develop proper documentation systems to issue KCCs to women where the land is in the name of the menfolk who do not reside in the rural area [jobs in the cities/army etc] or face similar other situation and the land is cultivated by the wife.

ix. **Distress sale - need for pledge loans:** Distress sale by small/marginal farmers to square off their debts or for immediate consumption purposes soon after harvest is quite common. According to the Report of the Inter-Ministerial Task Force on Agricultural Marketing Reforms, micro-level studies reveal that about 50% of the marketable surplus of small/marginal farmers is disposed off in distress sale. It is normal for a farmer to get 10-15% discounted price for spot payment for his produce. **Pledge loans to farmers need to be liberalised and encouraged to help the farmers to overcome this problem.**
x. **Credit business potential in marketing infrastructure:** The banking system needs to develop credit business potential of financing projects for improving/modernization of markets, storage including cold storage facilities, rural based transport operators, etc.

xi. **Negotiable warehouse receipt:** There is a need to encourage instruments based or secondary markets of agriculture produce. The constraints in improving the negotiability of warehouse receipts need to be removed.

xii. **Pariwar Bima Policy:** An integrated micro insurance policy providing floating cover for various risks i.e., hospitalisation of husband, wife and dependents, natural death, accidental death, permanent total or permanent partial disability and loss/ damage to dwelling unit etc., may be introduced with government support for the poor. The Panchayats and NGOs/ Self Help Groups could be the delivery arrangement for reaching a large number of clients. The government may meet a part of the premium cost as a life saving support towards a safety net for the poor.

xiii. **Rural Insurance Development Fund:** A Rural Insurance Development Fund may be created to take up development work for spreading rural insurance.

xiv. **Crop Insurance:** Crop insurance is covering about 14% of the farmers. The need is to expand the cover to all farmers and all crops in a time bound manner. The scheme needs to be made more farmer friendly and the premium reduced.

xv. Establish **Credit Counseling Centres** where severely indebted farmers can be provided with a **debt rescue package** of information in order to get them out of the debt trap, and thereby save them from committing suicide.

xvi. Establish in every block a **Self-help Group Capacity Building and Mentoring Centre** in order to equip members and managers of SHGs with the needed management, marketing and accounting expertise. The use of Kisan Call Centres needs to be popularized.

xvii. Develop and introduce an integrated credit-cum-crop-livestock-human health insurance package.

xviii. Promote credit and insurance literacy through the **Every Village a Knowledge Centre** movement. For this purpose, introduce policies for more extensive use of Community Radio linked to the internet/ cell phone.
6.4. **Technology:**

i. Technology is the prime mover of change. Both technology fatigue and technology gap should be avoided. This will call for revitalization of research, education and extension systems. It is suggested that all ICAR institutions and Agricultural Universities may commemorate 2006–07 as the **Agricultural Technology Year**. The major aim of this year should be to strengthen participatory research and knowledge management with farming families and the organisation of about 60,000 Lab to Land programmes in the area of post-harvest technology and value addition to primary products. Farm schools should be established in the fields of farmer-achievers in order to foster farmer to farmer learning of new technologies.

ii. Agricultural scientists should state the performance of new varieties and technologies in terms of **net income per hectare**, and not just in terms of yield per hectare. The aim of technological transformation of farming should be to enhance income per hectare on an environmentally sustainable basis.

iii. There should be a proper match between production and post-harvest technologies and a post-harvest technology wing should be added to every Krishi Vigyan Kendra. Also, Lab to Land demonstrations should include post-harvest technology. **About 60,000 Lab to land demonstrations may be organized in the area of post-harvest handling, processing and value addition during 2006-07 to mark the 60th anniversary of our independence. Many of them should be organized in dry-farming areas, where millets, pulses, oilseeds and cotton are grown.** The help of CSIR and the Central Food Technology Research Institute (CFTRI), Mysore should be taken by ICAR while designing the Lab to Land programme. The demonstration should be so designed that they also serve as training ground.

iv. For landless agricultural labour (both women and men), the aim should be to convert them into skilled workers, thereby adding economic value to their time and labour. The training should be in skills which can help in organizing market-
driven enterprises and the training methodology should be based on the principle of learning by doing.

v. Management procedures which can confer the economy and power of scale to small and marginal farm families, such as Small Holders’ Cotton and Horticulture Estates should be popularized. In such estates, production and biomass utilization can receive concurrent attention. Average farm size is going down steeply, and Farmers’ SHGs in the form of joint management units like the Cotton, Horticulture, Aquaculture and other Estates are urgently needed. The SHG movement should cover both the production and post-harvest phases of farming.

vi. Value addition to biomass will help to generate skilled jobs. Rice occupies the largest area in the country and the opportunities for generating more jobs and income by establishing Rice BioParks. Similarly, eco-boards can be produced from cotton stalks.

vii. There should be a pro-nature, pro-poor and pro-woman orientation to technology development and dissemination. Organic Farming and Low External Input Sustainable Agriculture (LEISA) techniques should be promoted along with Integrated Natural Resource Management and Integrated Pest Management (IPM) techniques. The role of women, both as farmers and farm labour is critical for the success of eco-farming practices. Hence, all programmes designed to foster access to technologies must be gender sensitive.

viii. Agricultural and Rural Universities, Home Science colleges and Research Institutes should foster participatory research and knowledge management systems with farm women and men. They should identify farm families from whom other farmers can learn (land to land transfer of technology). Farm Schools should be established in the fields of such farmer-achievers as recommended in the first report of NCF.

ix. New technologies like biotechnology (BT) and Information, Communication Technology (ICT) should be demystified and a cadre of Rural Farm Science Managers should be developed by training a couple of women and men members of every Panchayat/ local body in the management of new technologies, such as
the establishment of refugia in Bt Cotton fields and the detection of spurious seeds by using the Bt detection kit developed by the Central Institute for Cotton Research, Nagpur. Under the 73rd Constitution Amendment, the responsibility of Panchayats includes agriculture and agriculture extension. **Therefore, a Scientist – Panchayat linkage is the need of the hour.** Genome Clubs may be organized in village schools and KVKs to spread genetic literacy. Illegal release of genetically engineered crop varieties like Bt Cotton should be stopped. Spurious seeds will ruin the spread of useful technologies.

x. Inputs are needed for output. Hence, the right inputs should be available at the right time and place at affordable costs. Input supply systems should become farmer-friendly and also controlled by Farmer Self Help Groups to the extent possible. Quality standards should be enforced. The package of technology to be effective must be accompanied by an appropriate package of services in the areas of extension and input supply.

xi. Energy is a key input. The energy sources needed by farm families, both electricity and diesel, should be available in a reliable manner and at affordable price. In addition, solar energy could be tapped where economical. There should be a Panchayat-led integrated energy generation and management movement.

xii. ICT should be effectively harnessed to empower rural men and women through the Every Village a Knowledge Centre Movement with farming system and season specific information.

6.5.1 **Market:** Ultimately, it is only opportunities for assured and remunerative marketing that will determine the economic viability of farming both as a way of life and a means to livelihood. Market reform should begin with production planning, so that every link in the cultivation-consumption-commerce chain receives adequate and timely attention.

6.5.2 The existing State Land Use Boards are not equipped to provide proactive advice to farmers on land use planning. There is an urgent need for a **National Land Use Advisory Service, linked to State and Block Level Land Use Advisory Services** on a
hub and spokes model. These can be virtual organisations with the capacity to link land use decisions with ecological, meteorological and marketing factors on a location and season specific basis. The National Land Use Advisory Service can be linked to the proposed Indian Trade Organisation (ITO) as described later. It should have continuous contact with IMD, ISRO, Agricultural Universities and Departments, Commodity Exchanges and Futures Markets, APEDA, Commodity Boards and all credible national and international sources of information on domestic and international markets. The Land Use Advisory Service should cover crop and animal husbandry, horticulture, inland fisheries, forestry and agro-forestry, and have the capacity to proactively assess potential surpluses and shortages of essential commodities.

6.5.3 The State and Block level Land Use Advisory Service Organisations should have appropriate linkages to data providers at the State and local levels. The Block level Advisory Service can be located in the ISRO supported Village Resource Centres under the Mission 2007: Every Village a Knowledge Centre Movement.

6.5.4 Land use advice should be based on the quantity and quality of the available irrigation water and temperature. The National and State Level Land Use Advisory Services should also monitor the state of crops and issue timely warning on emergent surpluses and shortages. If this is done, situations like the recent onion shortage crisis can be avoided. Without economically and ecologically sound and proactive advice on land and water use, farmers will have to fend for themselves in taking decisions on what to grow. With the spread of agricultural globalisation, this can be disastrous to the economic health of farmers.

6.5.5 Amendment to Acts/legal instruments: The Essential Commodities Act and other legal instruments including the State Agriculture Produce Marketing Committee Acts [APMC Acts] relating to marketing, storage and processing of agriculture produce need to be reviewed in order to meet the requirements of modern agriculture and attracting private capital in this sector. We are glad that the Union Ministry of Agriculture has already taken action in this area.
6.5.6 **Periodic rural market:** There is a need for focused attention for improving the rural periodic markets, which are the first contact point for the farmers and also improving the infrastructural facilities at the regulated markets.

6.5.7 **Role of the APMCs/SAMBs:** The role of the APMCs/State Agriculture Marketing Boards need to change from regulatory focus to promotion of grading, branding, packaging and development of distant and international markets for the local produce.

6.5.8 **Commodity-based farmers’ organisations:** Commodity-based farmers’ organisations should be promoted to facilitate direct farmer-consumer linkage.

6.5.9 **Long supply chain – farmers’ organisations – Direct sales:** The supply chain is long and the intermediaries add their margin with very little/no value addition, leading to increase in the price paid by the ultimate consumer and low share of the producer. Farmers’ organisations/direct sale by farmers to consumers should be promoted.

6.5.10 **Post-harvest Operations:** The losses in harvesting, threshing, farm storage, packaging and transportation from farm to market are substantial resulting in huge loss to the farmer and the nation. The extension staff/PRIs could play an important role in educating the farmers in better post harvest management practices. As stressed earlier there is a need for introducing a Post Harvest Technology Wing in every Krishi Vigyan Kendra [KVK].

6.5.11 **MSP Implementation:** Implementation of MSP across the regions needs considerable improvement. Minimum Support Price arrangement needs to be put in place for many important crops other than paddy and wheat. These include for coarse cereals like millets. Without MSP support, advice to farmers on crop diversification could lead to disastrous results.
6.5.12 MIS: The price behaviour of sensitive commodities needs to be closely watched particularly during the glut periods for need-based intervention under the ‘Market Intervention Scheme’ [MIS] of the Government of India.

6.5.13 Import Tariffs: Import tariffs on farm products produced in resource poor regions deserve to be carefully monitored and maintained at such levels as to provide sufficient incentives to dryland farmers.

6.5.14 Pre–production Agreements to sell: Pre-production agreements for sale between the farmers and corporate houses/processing companies/others are being increasingly used in the case of certain vegetables/ fruits/ medicinal plants etc. These agribusiness models are being loosely referred to as ‘contract farming’ though in many of these cases there is no formal contract between the farmers and the prospective buyer. The advantage of such arrangements could be biased in favour of the agribusiness organisation. However, there are beneficial effects of such arrangements to the farmers in the matter of access to adequate/timely credit, good quality inputs, new technology, employment generation, introduction to new crops, separation of production and marketing risks and better farm practices etc. The need is to develop a comprehensive, clean, equitable and farmer centric model agreement, which cannot be abused against the farmers. Special care needs to be taken regarding clauses dealing with quality standards, withdrawal conditions, pricing standards, paying arrangements, acts of God clauses and arbitration mechanism. Till such a code of conduct is introduced and the farmers are empowered by formation of groups/cooperatives to deal with the agribusiness unit on their behalf, one has to be rather cautious about these arrangements.

7. Thus, the National Agricultural Renewal Year Programme of 2006-07, should deal concurrently with soil health enhancement, augmentation of the area under irrigation coupled with efficiency and equity in water use, credit and insurance reform, technology upgradation and dissemination, and farmer-centred marketing. The aim of the Agricultural Renewal Programme will be enhanced productivity per units of arable land and irrigation water, higher profitability, increased on-farm and off-farm employment
opportunities and long-term environmental sustainability. Distress hot spots should receive priority attention.

8. In a globalised economy, we should develop appropriate institutional instruments and policies to safeguard the livelihood security of nearly 70% of our population who depend on crop and animal husbandry, inland and marine fisheries, forestry and agro-forestry and agro-processing for their work and income security. Risk Mitigation and Price Stabilization Funds will be needed. All Technology Missions and the Small Farmers’ Agri-business Consortium (SFAC) should be restructured under competent professional management. Each Mission should have measurable time-bound goals. The Mission Director, an eminent professional, should be in position at least for a period of 5 years.

9. Farmers need appropriate institutional support to enhance their agricultural competitiveness. Institutional support to confer on small farm families the power and economy of scale is vital to enhance the productivity and profitability of small farms. Multiple livelihood opportunities are essential for ensuring the income security of resource-poor farming families, particularly in rainfed semi-arid, arid and hill regions. Mixed farming and improved post-harvest technology leading to value addition to primary products can help to achieve this goal.

10. The Union Minister for Commerce and Industry and the Government of India have done a commendable job in safeguarding the interests of our farm women and men in the recent negotiations at Hong Kong. They have put together a broad-based coalition of the concerned. Postponement of agreement in agricultural negotiations will however prolong the unequal trade bargain entered into at Marrakesh in 1994. As a national self-empowerment measure, we should consider establishing an Indian Trade Organisation (ITO) and our own boxes for domestic agricultural support on the model of WTO’s Blue, Green and Amber Boxes. The value of our annual agricultural production including livestock in 2002-03 was Rs. 5,60,516 crore1. The value of our

---

exports of farm commodities in 2002-03 was Rs. 34,654 crores (6.18 % of total agricultural production). Thus only a small proportion of our agricultural commodities enter the global market, since with a population of over a billion, there is a large home market. **Hence, we must segregate the very modest support we extend to our farmers into two groups – those which are of the nature of life and livelihood saving support to small farm families, and those which could be considered as trade distorting in the global market.**

The Indian Trade Organisation (ITO) can be a virtual organisation, specializing in WTO affairs. It can serve as a brain and information bank for enabling Government to take informed and proactive decisions. It can provide timely advice on potential surpluses and shortages in major agricultural commodities, by maintaining a trade watch. The Indian Trade Organisation should serve as a friend and guide to small farm families and should provide proactive advice on land use and crop planning. It should help to save resource poor farm families from the onslaught of the subsidy, technology and capital driven agri-business paradigm of OECD countries. **For this purpose, the proposed National Land Use Advisory Service can function as an arm of ITO.** In addition, ITO should help to impart trade and quality literacy through the national network of Village Knowledge Centres. It should monitor the arrangements for sanitary and phytosanitary measures and ensure that the codex alimentarius standards of food safety are maintained. The ITO will help to build a long-term memory system in relation to home and external trade and help checkmate adverse global trade trends by stimulating timely national action.

11. A schematic outline of the proposed institutional structures for safeguarding lives and livelihoods in rural India is given below:

---

2 Agricultural Statistics at a Glance 2004, Ministry of Agriculture, Govt. of India
Indian Trade Organisation (ITO)
(Professionally-led, 21st Century Virtual Organisation established by the Ministry of Commerce & Ministry of Agriculture and Food)

Two Specialised Wings

Farm Commodities consumed nationally (about 93%)
Ministry of Agriculture and Food
National and State Land Use Advisory Service
Livelihood Security Box
- Life saving support
- Implementation of Special Products (SPs) and Special Safeguard Mechanism (SSM)
- Tariff protection
- Quantitative restriction on imports

Enlarging the basket of Farm and Non-farm Commodities for the export market (about 7%)
Ministry of Commerce
WTO Regulations
Market Intelligence and Early Warning

12. Without the support of appropriate institutional structures, farm families will face increasing distress. It should be emphasized that the proposed ITO should accord priority to problems characteristic of the ‘production by masses’ category of farming. It should continuously emphasise the contrasting policy support needed by farm women and men engaged in subsistence farming, as compared to large agribusiness enterprises.
13. The proposed National and State level Land Use Advisory Services could be a part of ITO since this will help to ensure that the proactive advice on land and water use is based on the best available assessment of home and external trade opportunities.

14. **Launch of the Year of Agricultural Renewal Movement**: This movement which will cover the crop year of 2006-07 should be launched with the support of State Governments, Farmers’ Organisations, Business and Industry, Academia, Civil Society Organisations, Panchayati Raj Institutions and Mass Media. The year should end with the adoption by Parliament of a **National Policy for Farmers**, which will help to assure farm women and men that “Jai Kisan” is not an empty slogan. NCF will provide to the Ministry of Agriculture a draft National Policy for Farmers in April 2006, so that it can be widely discussed with farmers’ organisations during May - December 2006 and finally adopted before the 60th anniversary of our independence. We must put faces before figures, if we are to understand the sad plight of farm families. To assure farmers that Government measures agricultural progress not merely on the basis of production targets, but also on the basis of real growth in farmers’ income, figures on annual growth rate in farmers’ income should be given. Such a change in mindset, which regards farm families as the custodians of food security and national sovereignty and not just as “beneficiaries” of small Government programmes, will become explicit by redesignating the Ministry of Agriculture as the “**Ministry of Agriculture and Farmers’ Welfare**”.

15. The various components of the Year of Agricultural Renewal can be discussed and finalized by the Agriculture Coordination Committee chaired by the Prime Minister and the NDC Committee on Agriculture chaired by the Union Minister for Agriculture and Food. State Governments and Panchayati Raj Institutions will have to play the principal role in developing the precise strategies for soil health enhancement, water conservation and equitable and efficient use, credit and insurance, technology choice and delivery, and home and external marketing. The Government of India will have to take urgent steps to protect the over 600 million strong Indian farming community from the onslaught of the highly subsidized agri-business paradigm. International prices of farm commodities often give the wrong impression that farmers in OECD countries are more
efficient. According to Oxfam, the United States provided to about 25000 cotton farmers nearly US Dollars 3.8 billion in subsidies during 2004. No wonder they captured 40% share of global trade in cotton. The MSP for cotton should be worked out on the basis of what an undistorted price of cotton per quintal would be. **The need to announce an advance bonus of Rs. 550 per quintal is urgent in the case of cotton.** It should be noted that cotton farmers constitute a large proportion of those who have committed suicide.

16. **Indian Farmers and Bharat Nirman:** Bharat Nirman will help to foster job-led economic growth in villages and bring about a shift from unskilled to skilled work in the case of women and men without assets like land, livestock or fish pond. Improved communication (roads and telephones) and provision of electricity will help to open up new opportunities in the rural manufacturing and trade sectors. Gandhiji’s dictum that “Gram Swaraj is the pathway to Poorna Swaraj” should be the guiding spirit behind Bharat Nirman.

17. **We offer the following suggestions to ensure that the new deal to rural India also results in a new deal to farm and fisher families.**

17.1.1 **Consultation and Consensus:** Ten million ha of additional land are to be brought under irrigation by 2009. This will consist of the following steps:

   i. Completion of ongoing major and medium irrigation projects: 4.2 mha
   ii. Minor irrigation
   iii. Surface water: 1.00 mha
   iv. Ground water: 1.80 mha
   v. Enhancing utilization of completed projects 2.00 mha
   vi. Ground water development for small and marginal farmers, tribal and Dalits: 1.00 mha
17.1.2 As mentioned earlier, there are ongoing debates in all these areas from the environmental, political and social points of view. Frequently matters have to be settled by courts. Therefore the precise strategy for irrigation water security should be discussed in multi-stakeholder consultations at the State level as soon as possible so that continuous conflicts and litigation can be avoided.

17.2 Capacity Building: At least one woman and one male member of every one of the about 240,000 Panchayats/local bodies should be trained to become Members of a Bharat Nirman Corps. Bharat Nirman will then become everybody’s business. The training of the Members of the Bharat Nirman Corps can be done by Agricultural, Rural and Women’s Universities, IITs and by appropriate NGOs, Farmers’ Organisations, NABARD and Financial Institutions and Business and Industry.

17.3 Care and Management of the Infrastructure: Steps should be taken to ensure that there are adequate funds and institutional structures to maintain and improve the infrastructure created at enormous expenditure. The Gram Sabha should be involved in the process of providing oversight and advice.

17.4 Convergence and Synergy: At the local level, it is essential that there is convergence and synergy among other large social and human development programmes such as the National Rural Employment Guarantee Act and the National Rural Health Mission. Such measures would make the programme for Agricultural Renewal inclusive, ensuring attention to the livelihood security of agricultural labourers and landless families. Priority may be given to the integrated implementation of all these programmes in the Farmers’ distress hotspots in every State. The 500,000 Members of the proposed Bharat Nirman Corps can become the grassroot voices for the Gram Swaraj and Jai Kisan Movements.

18. Knowledge Connectivity: NCF is grateful to the Government of India for accepting the recommendation made in its second report (August, 2005) that Knowledge Connectivity should become fundamental to physical connectivity under the Bharat
Nirman programme. We welcome the following statement in the revised Bharat Nirman document regarding Knowledge Connectivity:

“The Government is committed to expanding rural connectivity through a slew of measures so that rural users can access information of value and transact business. This will include connecting block headquarters with fiber optic network, using wireless technology to achieve last mile connectivity and operating information kiosks through a partnership of citizens, Panchayats, Civil Society Organisations, the Private sector and Government.”

19. The National Alliance for Mission 2007: Every Village a Knowledge Centre facilitated by NCF provides a platform for partnership for achieving the goal of knowledge connectivity under Bharat Nirman. NCF recommends that Government may review its policy towards Community Radio, since a combination of the Internet/ cell phone and community radio will help to take timely information to farmers even in the remotest parts of the country.

20. In 1995, the Supreme Court of India ruled, “air waves or frequencies are public property”. The principle is the same as for seawater enshrined in the immortal Dandi march of Mahatma Gandhi. A successful merger of tele-centre technologies and the radio will help to usher in an era of knowledge revolution in rural India. Efficient disaster management and mitigation will be greatly facilitated by such a step. We therefore recommend that Village Knowledge Centres (VKC) may be permitted to apply for a community radio license. The eligible organisations should also include Gram Sabhas, Cooperatives, ICT-Self Help Groups promoted by NABARD, NGOs and Educational Institutions.

21. As Community radio applicants generally represent rural, remote and deprived communities, with limited funds and access to Delhi, a single window clearance should be given for CR licenses. It is important to recognise that the applicant, being a small outfit in rural areas will not be able to access various departments in government for
clearance. NCF suggests, that the extension and provision of community radio licences to village knowledge centres is seen as a part of Bharat Nirman. In the light of the above, all clearances and documents, including the Wireless Operating License, should be granted within a period of three to four months from the date of receipt of the application. The Community Radio license should be valid for a period of five years from the date of operationalising the radio station, with the option to request an extension for another five years. No license fee should be levied on the CR license holder. The requirement of furnishing a bank guarantee at the time of applying should ideally be done away with, or should be a token amount of Rs 5,000. A community radio station may be permitted to cover an area of minimum of 10 kilometres radius, for which a minimum transmitter power of 100 watts is required. However, in case of hilly, isolated and sparsely populated terrain, a more powerful transmitter or a wider coverage area may be required to reach the target community. In such cases, the transmitter power may be fixed according to topographic and demographic requirements. Broadcasting using transmitters up to half a watt should be de-licensed. The number of frequencies to be allotted for community radio should ideally be fixed at three within a particular coverage area for optimisation.

22. In an era of globalisation and bottom-up approaches to development, Community Radio can act an important medium in strengthening grassroots and mainstream linkages; act as a true people’s medium and contribute towards creating a vibrant, aware and informed community, the hallmark of a true democracy. As one of the signatories to the process of the World Summit on Information Society, India is committed to ensure a political atmosphere that enables the creation of a “people-centred, inclusive and development-oriented Information Society, where everyone can create, access, utilize and share information and knowledge.” Extending to the citizens of India, a right over airwaves would be an essential measure in both these regards.

23. A Community Radio Station attached to VKCs may be permitted to cover an area of approximately 10 kilometers radius. In the case of hilly areas as well as fishing zones in oceans, a wider coverage will be needed. Broadcasting using transmitters up to half a
watt should be delicensed. The Community Radio license should follow the programme and commercial codes of the All India Radio. A forward-looking Community Radio Policy which will be in keeping with the spirit of the Right to Information Act is the need of the hour. Knowledge and skill empowerment of farm families is essential for achieving the goals of the Year of Agricultural Renewal.

24. To sum up, we should not remain silent spectators to a steady agricultural decay. Both human security and national sovereignty are at stake. Overall economic growth rates have little meaning if we do not look after the economic health and survival of over 60% of our population. The Year of Agricultural Renewal programme, if implemented with speed and dedication, can help to launch the country on the path of an ever-green revolution in agriculture characterized by continuous improvements in productivity and profitability without associated social or ecological harm. Improving small farm productivity, as a single step, will make the largest contribution to the eradication of hunger and poverty. This, together with the generation of market driven non-farm livelihood opportunities through the proposed ICAR-CSIR 60,000 Lab to Land demonstrations in post-harvest technology and agro-processing will help the country to realize the full benefits of Bharat Nirman.
CHAPTER II

STRENGTHENING AGRICULTURAL RESEARCH:
TOWARDS SCIENCE-LED EVERGREEN REVOLUTION

2.1.0 Introduction

“However efficient the organization which is built up for agricultural demonstration and extension, unless that organization is based on the solid foundations provided by research, it is merely a house built on sand”

(Royal Commission on Agriculture, 1925)

2.1.2 Science and technology are the engines of agricultural growth and development. This was amply demonstrated in the Green Revolution process in India triggered by the development and widespread adoption of high yielding varieties (HYVs) of rice and wheat and ushered in by the synergistic congruence of technological, political and socio-economic forces in 1968. Green Revolution technologies played a major role in increasing food supplies, in lowering and stabilizing food prices, in increasing farm incomes and in generating additional income and employment in the non-farm economy. Even poor producers were able to internalize their production and employment benefits to improve their incomes and food security. Poverty levels in rural areas declined and the country moved from food deficit to food surplus in two decades, thanks to high growth in total factor productivity.

2.1.3 Early projections expected these trends to continue though indications were there in the mid-1990s that a deceleration of the rate of technical change could erode these gains significantly. With respect to the vanguard crops - rice and wheat, and leading regions - northwestern India, there is indeed a deceleration. Wide yield gaps continue for all crops at various levels. New challenges have also emerged even as the traditional concern of sustained food security permits no room for complacency. Poverty and hunger, despite significant improvement are still at unacceptable levels as India is home
to nearly one-fourth of the World’s hungry and poor. It is becoming obvious that past paradigms and institutions will not serve either the cause of growth or of poverty alleviation. No wonder, India is off track in achieving the UN Millennium Development Goals, particularly in the areas of hunger and poverty reduction.

2.1.4 Today, Green Revolution has waned and India’s agricultural growth rate in recent years has slipped below the population growth rate. This has implications for economic growth, food security, equity and rural welfare. The mid-term review of the 10th Plan had also revealed that the progress is way off the track in meeting all the targets set for the Plan period and beyond. This trend must be reversed to help achieve the desired agricultural growth rate of about 4 percent per annum. This requires a multi-pronged strategy, developed around technology flow. We have analysed the nation’s agricultural research and technology development system with a view to suggest as to how the R&D sector should be strengthened and reoriented to play the pivotal role in creating a science-based and knowledge-led evergreen revolution. We are convinced that science and technology will assume even greater role than in the past, but ‘more of the same’ will not serve the cause. Contemporary challenges and opportunities would demand a reorientation of agricultural R&D institutions, strategies, and a new paradigm to steer these.

2.2.0 The State and Trend of Food, Agriculture and Food Security

2.2.1 During the past over 40 years (between 1962-63 and 2003-04), spanning the Green Revolution era, foodgrains production increased from about 83 million tonnes to about 200 million tonnes, primarily due to increase in cereal production, particularly rice and wheat, from 70 million tonnes to nearly 187 million tonnes (Table 1). Oilseeds, sugarcane and cotton productions had also increased by 2 to 3 times. But, the production of pulses remained more or less stagnant, around 12 million tonnes, although in recent years there is some acceleration. As regards livestock production, from 1970 onwards, the growth has been phenomenal, multiplying from 23 million tonnes in the triennium ending (TE) 1972-73 to 88 million tonnes in the TE 2003-04. Today, with an annual
production of nearly 100 million tonnes, India is the largest milk producer in the world. Fish and eggs productions had also multiplied 5 to 6 times.

2.2.2 **The quantum jumps in the productions were realised through quantum jumps in yield.** For instance, cereals yield increased from 750 kg/ha in TE 1962-63 to 1915 kg/ha in TE 2003-04 (Table 2). It is heartening to note that about 70 to 75 per cent of the production increases in most of the commodities were through increases in yield per hectare. It may be further noted that while the Green Revolution had occurred essentially in wheat and rice, its spill-over effect was visible in other commodities and production systems.

2.2.3 However, as seen in Figures 1 and 2, production of cereals, oilseeds, sugarcane and cotton from 1996 onwards has remained stagnant and at times even declined. Nonetheless, lately (during 2004-05), cotton production has shown remarkable progress and has increased to about 243 lakh bales in 2005 from about 138 lakh bales in 2003. During the same period, the cotton lint yield has increased from less than 300 kg/ha to over 500 kg/ha (partly attributed to the rapid adoption of Bt Hybrid cotton varieties). Fortunately, although slightly decelerated, livestock and fish productions continue to maintain steady growth (Figure 3).

Source: Agricultural Statistics at a Glance 2004
2.2.4 During the next 5 to 15 years (by the years 2010 and 2020), foodgrains production will need to be increased by about 45 and 90 million tonnes, respectively, from the current level (Table 3), requiring an annual growth rate of 1.96 percent, against 2.18 percent registered during 1995 to 2000. Human demand for high value food products, namely, fruits, vegetables, milk, meat, egg and fish, as evident from the past consumption trend (Table 4), and further propelled through income growth (GDP growing annually by 7 to 8 percent), is projected to increase by about three-fold towards the year 2020 at a high trend growth rate of about 4 to 5 percent (against a trend growth rate of about 1.96 percent for foodgrains) (Table 5).

2.2.5 Given that nearly 600 million Indian people (about 60% of the total population are directly dependent on agriculture, comprising about 120 million farm families, the country, of necessity, aims to meet its food and agricultural demand almost entirely from its domestic production. Thus, the demand projections closely match the production targets (Table 6). As seen in Table 6, area under foodgrains in 2010 will be only 121 million ha against 124 million ha in TE 1994-95. Therefore, the projected additional production towards the years 2010 and 2020 must accrue entirely through yield increases of about 50 to 100 percent over the base year TE 1994-95 (Table 7).

2.2.6 As seen in Figure 4, the average yield at the national level is required to be improved by 33 per cent for rice, 35 per cent for wheat, 16 per cent for coarse cereals, 66 per cent for pulses, 37 per cent for vegetables and 72 per cent for fruits by 2010 over the base year 1994-95. By 2020, the yield level over the base period yield is required to be improved by 56 per cent for rice, 62 per cent for wheat, 36 percent for coarse
cereals, and 116 per cent for pulses. The production of livestock and poultry products must be improved by 70-80 per cent by the year 2010 and 136-157 per cent by the year 2020. This level of yield improvement requires serious efforts on the part of the National Agricultural Research System (NARS). The emphasis for achieving the required increments in yield levels must be placed on regions where the current yield levels are low.

Figure 4. Required Improvement in the Productivity Over the Year 1994-95

2.2.7 Annual total agricultural production is a function of extent of cultivated area, yield per hectare and cropping intensity. The cropping intensity (currently around 130 percent) and yield per ha largely depend on water availability (irrigation intensity), plant nutrient application and availability (fertiliser consumption) and on extent of area coverage under quality seeds of modern varieties – the three pillars of the Green Revolution, of course, duly supported by appropriate policies and services. As seen in Table 8, net cropped area increased from 135 million ha in 1961 to 142 million ha in 1981 and since then has stagnated and even marginally decreased. Area under irrigation has more than doubled from about 25 million ha in 1961 to 55 million ha in 2001. Quantum jump had occurred in fertiliser consumption which increased from 0.34 million tonnes in 1961 to over 16 million tonnes in 2001 (in elemental terms, the nutrient
supply increased from less than 10 kg NPK per ha to over 90 kg NPK per ha). The coverage under High Yielding Varieties (HYVs) of rice and wheat ranges from about 60 percent to almost 100 percent, varying from State to State and region to region within States, the adoption being much higher under irrigated conditions as compared to that in rainfed and other non-congenial settings.

*Figures relate to 2002-03; Source: Agricultural Statistics at a Glance 2004

2.2.8 In recent years, however, the three pillars of the Green Revolution have weakened. The growth in fertiliser use has greatly decelerated. Non-availability of quality seed in adequate quantity, at desired time and at reasonable cost, is a major constraint. The irrigation growth has also decelerated and has often accentuated salinity and water logging problems. The use efficiency of all the three factors has thus greatly deteriorated. The rates of adoption of new technologies have also been far below its expected level (Table 9). These adverse trends of resource use and technology transfer are certainly responsible for the sluggishness of Indian Agriculture in recent years.

2.2.9 Table 10 gives the composition of agricultural economy of different States as well as of the country as a whole. The contribution of crops sub-sector to the agricultural economy has decreased from 76% in 1981 to 66% in 2002 whereas the
contribution of livestock sub-sector has increased from 18% to 25% and that of fisheries from 1.9% to 4.4%. Considerable differences amongst the States regarding magnitudes of contributions of the various sub-sectors have emerged over the years. As regards crops, in several States, such as Madhya Pradesh (where the contribution of crops has increased from 70% to 75%), Maharashtra, Orissa, Tamil Nadu, Uttar Pradesh and Assam, the contribution was over 70%. The livestock sub-sector contributed over 30% to the agricultural economy in Rajasthan, Punjab and Haryana and between 25% to 30% in the States of Andhra Pradesh and Himachal Pradesh. The fisheries sub-sector had relatively high importance in the States of Goa, Andhra Pradesh, Assam, Gujarat, Orissa and West Bengal. These trends must be internalised while allocating resources and setting priorities for research and technology development programmes in different States and regions.

2.2.10 FAO estimates reveal that the number of undernourished people in India increased from 216 million in 1990-92 to 221 million in 2000-02, although the number had decreased to 203 million in 1995-96 (Figure 5). During the same period, in China, the number of undernourished decreased from 194 million in 1990-92 to 146 million in 1995-96 and to 142 million in 2000-02. **Micronutrient and vitamin A deficiencies posed greatest health problem in India.** As seen in Figure 6, in the year 2000, 57 percent of the pre-school children in India suffered from vitamin A deficiency against 41 percent in Sub-Saharan Africa and 16 percent in China. **This slow or even negative progress (in terms of absolute number of undernourished) in India’s food security, to a large extent, was related to the slow growth in already low income of farming households**, increasing from Rs 9,049 during 1969/70-1973/74 to Rs 11,223 during the year 1999/00-2003/04. **The income disparity between agricultural workers and non-agricultural workers doubled from 1:3 during 1979-84 to 1:6 during 1999-2004 (Figure 7).**

2.2.11 Despite a deceleration in rate of growth of human population in recent years, India’s projected total population in 2010 will be 1.19 billion, comprising 815 million rural people (68 percent of the total population). The agricultural population will
account for about fifty percent of the total population and 71 percent of the rural population. Poverty projection for 2006-07 suggests that of the 220 million of the people below poverty line, 171 million will be rural people, of which nearly 122 million will be farmers or their family members. **In other words, while poverty will continue to be essentially a rural phenomenon, the majority of the poor people will be from the farming community.** This is not difficult to understand as one sees the declining trend of the contribution of agricultural GDP to the total GDP. As seen in Table 11, during the past eight years, the post reforms era - 1995/96 to 2003/04, the agricultural GDP grew only by 1.86 percent per annum whereas during 1980/81 to 1994/95 it grew by 3.33 percent. The corresponding figures for the non-agricultural GDP were 6.95 and 6.56 percent, respectively. Further disaggregation shows that within agriculture the crops GDP had grown only by 1.18 percent whereas the livestock GDP grew by 3.7 percent.

2.2.12 There must be a paradigm shift from the concept of macro-level food security at the National level (i.e., the per capita availability of food) to nutrition security at the level of each individual child, woman and man. Nutrition Security is best defined as "physical, economic, social and environmental access to balanced diet and clean drinking water”. **The major cause of household and individual level food insecurity in our country is the lack of the minimum purchasing power essential for economic access to balanced diet. The famine of jobs/ livelihood opportunities leads to the famine of food at the household level, thus emphasizing the need for ensuring**
that our development strategies lead to job-led and not jobless economic growth. Farmers are also consumers and hence 70% of the consumers in India are also those who earn their livelihood in farming. Therefore, under our conditions enhancing agricultural productivity per units of land, water and labour is the speediest way of ending poverty-induced chronic undernutrition. Another problem of the Indian agricultural economy is that of the intensity (Table 12). It may be emphasized that the smaller the farm, the greater is the need for marketable surplus, so that the family has adequate cash income. With the increasing fragmentation of land and continuing decrease in average size of farm holdings, part time off-farm employment of marginal and sub marginal farmers would become a necessity for livelihood security. In this context, the newly enunciated National Rural Employment Guarantee Scheme, the Food for Work Programme and the National Food Guarantee Programme (proposed by NCF) could be extremely effective in enhancing livelihood security of the farmers and of other rural poor, particularly through strengthening skilled employment.

2.2.13 The intensity of small farms (<2 ha) in the country will further increase, reaching 83 percent in 2010/2011 (from 63 percent in 1960/61). About 45 percent of the total cultivated area will be operated by smallholders and the rest 55 percent will be operated by medium-and large holders, which together would constitute 17 percent of the total farming households (Table 12).

Source: Jha, Dayanatha, Presidential Address, 60th Annual Conference of Indian Society of Agricultural Economics
2.2.14 Agricultural Research must be refocused in a manner that science not only helps to enhance productivity, but also income through farming system diversification and value addition. Value-added employment involves a paradigm shift from unskilled to skilled work and from routine on-farm to value-added off-farm livelihoods. Over a third of the rural population is assetless, i.e., they do not possess land or livestock or fish pond. Concurrent attention to skilled on-farm and non-farm employment is essential for alleviating poverty and chronic undernutrition. Unfortunately, agricultural research institutions are yet to work in an integrated manner to achieve the triple goals of ‘more food, more income and more jobs”, all in an environmentally sustainable and socially equitable manner.

2.2.15 Our planning process over the past decades in the agricultural sector has been focused on increasing foodgrains production. All strategies have been addressed to the crop sector and rightly so, because focus was providing the foodgrains. But incidental to such planning process, the livestock sector got neglected and in its wake the landless and the marginal farmers, who constitute 58% of the rural population, never received due attention. Incidentally, this resource poor population sustains itself through 481 million livestock and 410 million poultry which serve as the most critical components of our rural production system.

2.3.0 Changing Contours of Indian Agriculture

2.3.1 Opening up of the economy and integration in global market implies dismantling of protective restrictions intended to safeguard national interests, and enhancing our competitiveness. Food self-sufficiency, maintaining low food prices, raising agricultural exports, and investments for upgrading production potential in a cost-effective and sustainable mode were overriding concerns. These generated a stream of protective and incentive instruments (all bunched in AMS) which need adjustments under the liberalized regime and imply massive restructuring of the price structure. Agriculture is responding to these forces as well as to changing IPR regimes.
2.3.2 The most profound shift pertains to **rapid privatization** in all domains - production, consumption, investment, technology, etc. and concomitant decline in State control. Alternative instruments and approaches are evolving to transform agriculture and a very important part of this ‘learning’ phase is a redefinition of the role of the State. Public goods, welfare imperatives, other regulatory needs, and other areas of market failure will continue to need government intervention. **A matter of concern globally is shrinking investment in international public goods.**

2.3.3 Policies and instruments which served well in yesteryears have either been overstretched or are untenable in the current scenario. There is consensus that the unfolding challenges of Indian agriculture can only be addressed through science and technology, and that a different R&D paradigm - a **national innovation system** integrating all facets of rural life and stakeholders would be necessary. **While Centrality of the efficiency mantra is essential for meeting the growth objectives, sustainability issues would also become critical.**

2.3.4 The agrarian structure is in a flux. There is inexorable downward pressure on farm size and increasing concentration in the lowest size-groups. Increasing migration and occupational restructuring are consequent responses discernible in the countryside particularly in hill and mountain and arid drylands. It is now realized that **smallholder farming must become viable and efficient.** This focus also underscores the importance of **employment and labour intensity of agriculture.**

2.3.5 Agricultural growth in recent years has thrown new sectors and regions into prominence. Livestock, fisheries, horticulture, specialty enterprises (spices, aromatic, organic) and value-added products illustrate this trend. **Market-driven diversification** in a global perspective has become the new paradigm driving future agricultural growth.

2.3.6 Rising capital intensity, particularly in the high-growth sectors of agriculture, has set in motion a new set of forces. Movement of industrial and foreign capital and entrepreneurial resources to agriculture, biased technical change, continuing infirmities in market and other infrastructure, varying knowledge- intensity of the sector
and other factors are ingredients of the evolving scenario which need to be monitored and regulated appropriately. **There is a real threat that left to the market, poor and small farmers will lag further behind.** The soaring imports of vegetable oils and pulses and depressing the domestic production of these commodities is a case in point. **Declining growth in public investments and eroding institutional infrastructure are other disturbing features of the current trend.**

2.3.7 World agriculture, particularly trade, places high premium on **quality.** **Public health and food safety concerns are central themes of global regulatory negotiations.** Indian agriculture has to respond to these. Equally important are sustainability of natural resources (particularly water) and other environmental externalities including global warming and climate change. These could cripple our productive capacity sooner than later. Market failure is widespread in these sectors and difficult regulatory measures confront us.

2.3.8 **The agricultural knowledge sector** will play a pivotal role in exploiting the new opportunities and containing the likely threats. A new philosophy, approach and strategy will be required even as we try to enthuse vigour and vitality in the existing R&D institutions.

2.4.0 **Overview of Agricultural R&D Infrastructure**

2.4.1 Agricultural R&D owes its origin, growth, and sustainability to public support as more than 85 percent of aggregate R&D funding comes from public exchequer. With more than 20,000 scientists and Rs. 30601 million expenditure, it is one of the largest systems in the world.

2.4.2 The public system has large and complex network of Central and State research/education institutions/universities, zonal research stations and co-ordinated research programmes (Table 13). The ‘D’ component has been with the States, under the control of State departments of agriculture. Its isolation has not been successful and there has been a **decline in the extension system across the board.** Consequently, the Centrally supported frontline extension system has grown covering frontline
demonstrations, KVKs (496 and by the year 2007 the Government aims to establish at least one KVK in each 527 district). Current thinking, however, appears to favour NGOs involvement.

2.4.3 The institutional edifice of the State R&E system continues to grow. The number of SAUs has grown from a mere handful in early seventies to 40 now. Unfortunately, funding levels have not kept pace with this and operational as well as scientific resources have degenerated. These trends fly against persistent advice to reorient resources and focus toward local R&D institutions.

2.4.4 Perhaps the most significant trend has been the growing involvement of private sector. This is welcome. However, its exclusive preoccupation with profits restricts its area of interest. The whole subsistence farming sector, the substantial body of new knowledge in public goods domain, poor and fragile eco-systems are examples. Public-private synergy is evolving as a new R&D ideology.

2.5.0 Investment in Agricultural R&D

2.5.1 Current R&D spending is estimated at about Rs. 31 billion annually. It is backed by more than 20 thousand scientists in the research/education sector alone.
Private sector participation has risen rapidly over the last decade and it now accounts for about 14 percent of funding (Table 14). The uptrend in public R&E funding has been consistent, except in more recent years when it has flattened. Operational support however has not kept pace with overall trends. The problem has been serious in the State system whose share in the total R&E expenditure has consistently declined over the past four decades (Table 15).

2.5.2 The edifice is large in nominal terms. In relation to the size of the agricultural sector, however, investment intensity is low. At 0.34 percent of agricultural GDP (Figure 8), research intensity is only half of the overall average for all developing
countries (0.6 percent) (Table 16). There is considerable inter-State variability in intensity of State funding (ranging from 0.08 in U.P. to 1.4 in H.P.) (Table 17). With the exception of a few States, commitment to R&E is not strong and in some States (UP, WB) the situation has deteriorated (Figure 9).

Figure 9. Per Capita State Domestic Product and Research & Education Intensity (2001-04)

Source: Pal, Suresh, 2005. NCAP, New Delhi
2.5.3 Dependence of State R&E on the Centre has grown. For outreach programmes also, Central support has become more important. It has been argued that this has crowded out support for hardcore R&E. The conceptual dichotomy between basic/applied research/development and institutions (Central/local) has to be translated in a clear funding policy.

2.5.4 Priority accorded to agricultural R&D is revealed by the fact that this large network was built mainly from domestic resources. There has been a slowdown over the last decade or so and this is reflected in restraints on recruitment of scientists. This has been attributed to the overall policy thrust on downsizing public bureaucracy. Current assessments argue for a need-based approach on this so that priority sector investments remain on track in real sense.

2.5.5 Yet, very modest external assistance has played a useful role in R&D capacity development. In the wake of the evolving IPR regime, global technology markets are tightening. This reinforces the thrust on domestic capacity building and external assistance has a key role to play in this regard. Public good research requires adequate support from public funds.

2.5.6 R&D needs are growing exponentially and substantially enhanced domestic funding is essential to address these. There are pronouncements at the highest level endorsing this. On the other hand, there is also the view that we do not need more of the same. Until the contours of a national policy on public R&D are redefined and clearly enunciated, managers of public finances will remain apathetic.

2.6.0 Scientific Manpower Resources

2.6.1 Scientific manpower is the most critical resource for R&D. There are no official estimates but a recent study shows that there are about 22,000 scientists in the NARS (Table 18); public sector institutions account for more than 95 percent of them. Public extension system is much larger, and taken together, professional manpower in public agricultural R&D appears impressive.

</table>

2.6.2 Skill level of scientists in the research and education system is comparable to the best. More than two-third of them hold Ph.D. degrees. The extension system, on the other hand, faces the problem of low proficiency and this has remained a matter of concern from the very beginning. In addition to efforts to upgrade the skill level through intensive training, this has also forced entry of better trained research and non-government personnel in extension system. A highly motivated and trained public extension system is essential to raise the knowledge intensity of Indian agriculture. Dismantled and ad hoc responses are inefficient.

2.6.3 The average age of scientists is growing and this has long-term implications for scientific productivity. This has happened due to divergence between attrition and replacement rates in recent past. Restrictions on recruitments in public sector has affected human resources adversely both by discouraging creation of new positions and by bureaucratic hurdles on filling vacancies.
2.6.4 More than three-fourth of the scientific manpower resources are in States which account for half of the national R&E expenditure. With nearly uniform salary patterns, this reveals structural weakness—support per scientist is significantly lower in the State system (Rs. 0.84 Million against Rs. 1.72 Million). As attention shifts back to strengthening local R&D institutions, this dichotomy will need to be addressed. There cannot be a ‘second rate’ psyche segregating scientists. Institutional dispersion of scientists reveals another constraint. Several ICAR and SAU units are below the critical size. This implies that we create hard infrastructure but often fail to back these up with adequate human resources (humanwares).

2.6.5 Matching human and other resources has not received adequate attention. Finally, there are two serious issues which need reiterating. These relate to decline in scientific manpower in the State system and stagnation in the Central system. This has happened during the phase when the research agenda expanded and diversified. This had consequences like loss of critical mass in research units and programmes. Second, lower support per scientist in the State system does not auger well for the future, particularly since these scientists are expected to play a larger role in research outreach functions.

2.7.0 Institutional Base for Agricultural R&D

2.7.1 Institutional linkages and research coordination are unique strength of the public R&D structure. Private R&D achieves excellence by concentrating high quality resources. This is beyond the reach of public systems, but synergies and complementarities offer similar opportunities. This requires careful planning, an area which has not been given much attention. Consequently, these institutions try to emulate the private sector research institute/laboratory model. This is not tenable logically besides nurturing waste and duplication. Redesigning national R&D must begin from this premise. This requires ‘out of the box’ thinking.

2.7.2 Without professionalizing and modernizing the public extension system, the tripod of research, education and extension cannot be completed. The most important source of synergy breaks down. This has been recognized since long but the resource
implications have kept reforms at bay. The segmented (Centre-State, research/education-extension) and departmental models tried in the past have not been successful. The unique nature of agriculture makes agricultural R&D different from other sectors and makes extension vital. The context is different and other providers are emerging. **A new ball game has been set up and our response has remained outdated.**

2.7.3 **The Green Revolution model of R&D organization is proving inadequate** in the current context for several reasons. An alternative national innovation system paradigm has been proposed which places the farmer (rather than commodity/resource or region) at the Centre and then weaves in the farming system, technology, markets, and other stakeholders. In fact, elements of this concept are emerging in market-led transformation occurring in the countryside but public institutions, including R&D, remain rigidly tied to the past. This approach calls for massive changes in existing institutions.

2.7.4 Clear enunciation of the roles of the Centre, States, local bodies, Panchayati Raj Institutions, private sector, and NGOs in a client-Centred R&D structure is a critical task. Public resources are getting scarcer and its deployment has to focus on efficiency. **Critical scientific and resource mass and modern management must back the human resources. A very strong policy and planning capacity has to be created.**

2.7.5 The emerging IPR regime will have profound implications for public R&D systems. The changing incentive climate will drive resources away from public to private goods and from long-term to short term gains. Both of these detract from the basic rationale of public investment in R&D.

2.7.6 The Central point is that powerful forces have been unleashed by the free trade movement. In countries which have pursued the path of protection for long and have developed institutions accordingly, this change calls for new rules of the game and new institutional arrangements. We have not even begun thinking about how these will affect the existing R&D edifice. **Time is not on our side,** particularly keeping in mind that several of the bilateral and regional trade agreements that our country has signed will
be in force within three to five years. **Post-Hong Kong breathing time space on most global agreements is hardly 10 years.**

### 2.8.0 Research Resource Allocation

2.8.1 R&D became a critical element of agricultural development strategy since the fifties and it has been reasonably well supported. The Green Revolution created a favourable environment and provided a model strategy. As the foodgrains demand-supply balance became manageable, the same strategy was adopted to tackle new and emerging research issues like regional disparities, resource conservation and sustainability, high-growth and high-value commodities, frontier technology sectors, WTO-related research issues and so on. Such initiatives absorbed additional resources which were liberally provided for nearly three decades. There was not much concern regarding resource allocation in this expansion phase; additional resources to implement new schemes (plan) and on-going programmes (non-plan) was the critical issue which became the main monitoring indicator as well.

2.8.2 Public resources gradually became stringent and research priorities, relevance, research productivity and other efficiency-related issues came to occupy centrestage in the nineties. Research resource allocation is the main theme in this debate which strives to create a ‘new look’ national innovation system. The following issues of macro dimensions deserve priority attention and redressal:

- As mentioned earlier, new (**plan**) and on-going (**non-plan**) dichotomy has long been the only resource allocation calculus invoked every five years. Non-plan activities have claimed more and more resources over time and the flexibility to shift resources to new areas has gone down in recent years. This has been the impact of dwindling resources on the one hand and rigidities in non-plan expenditures on the other. **The share of research in total agricultural development expenditure has also gone down.**
• A related consequence has been **decline in operational cost per scientist**. This has hit the State system more and their capacity has been seriously undermined. Functional allocation of research funds emerged as a major issue in the nineties.

• Public R&D embraces research, education and extension. In the last 50 years, the relative emphasis has changed. In the initial post-independence years, the strategy emphasized extension. The assumption was that there was adequate slack in the knowledge system which could be exploited. Over the next three decades, focus shifted to research and capacity building covering research programmes, institutions and human resource development. There has been a noticeable shift in emphasis in recent years and outreach has again come to prominence.

• Research domain includes upstream (basic/strategic) and downstream (applied, on-farm) components and since the reorganization of research in the sixties there has been a division of labour between Central and State institutions along these lines. It has been shown earlier that the Central component has grown faster in terms of investments. It has also moved in downstream areas significantly. It is now realized that **critical weaknesses lie in the State component and this must be addressed, especially keeping in mind that agriculture is a State subject.**

• There are other macro policy issues which have a bearing on allocation of public resources for research. Growth in private research capacity, possible impact of research complementarity and spill-in, use of domestic and external resources, are examples which have all been invoked in research resource allocation debates. The problem all along has been that **the NARS has never articulated a Research Policy Statement**. Not surprisingly, very little analytical attention has been paid to resource allocation questions.

2.8.3 **Current resource allocation profile reveals that there is greater emphasis on R&D activities.** The integrated approach adopted by the public system implies that resources are allocated to research, education/training, and extension. **Table 19 shows** that while almost everyone participates in research, more than 70 percent are involved in teaching/training and extension. Overall, 48 percent of all public R&E resources are
allocated to research, 19 and 33 percent are allocated to teaching and extension, respectively (Figure 10). Despite heavy back-up of support staff, nearly 11 percent of scientific resources are allocated to administrative chores. This amounts to more than a thousand full-time scientists - a waste no system can afford. As expected, Central research resources focus relatively more on research, but research resources allocated to administration is also higher. With little education responsibilities, the private system is able to dedicate more resources (60 percent) to research.

Figure 10. Percent Distribution of R&D Expenditure, 1999-2001

2.8.4 As regards commoditywise allocation, Figure 11 shows that a major share of agricultural research is crop focused. Foodgrains and horticultural crops, the mainstay of the national food system, account for about 40 percent. The other major groups - livestock and fisheries receive (together about 22 percent) less attention than their importance in agricultural GDP. Food security still remains a strategic concern and claims very high priority. Figures for the Central research sector (ICAR) indicate a more growth-focused allocation with 25 percent resources going to livestock and fish, whereas SAUs allocate only about 19 percent to this sub-sector. The ICAR has a strategic forward-looking role and the allocation profile substantiates this. The table also shows that ground level institutions (SAUs) target their research resources more locally. The emerging private sector is still highly selective in its allocation. The broad pattern of allocation at different institutions is consistent; more rigorous analysis at programme/project level is needed for in-depth analysis of rationality.

Figure 11. Research Focus of Scientist

![Research Focus of Scientist](image)

Source: Jha, Dayanatha and S. K. Pandey (2005), Research Resource Allocation, NCAP, New Delhi

2.8.5 Regional resource allocation analysis revealed that six agro-climatic zones — Trans-Gangetic, Central Plateau and Hills, Western Plateau and Hills, Southern
Plateau and Hills, East-coast Plains and Hills, and West-coast Plains and Hills accounted for more than 58 percent of all research resources. **Lower Gangetic Plains, Eastern Plateau and Hills, and Western Dry Region** were relatively under-emphasized (Figure 12). Strong State systems naturally contributed to regional capacity. ICAR followed a more balanced strategy and also factored in State capacity in its regional allocation. Congruence analysis indicated the need for higher marginal allocation to the zones neglected in the past.

**Figure 12. Percent Distribution of FTE Scientists by Ecoregions**

![Bar chart showing percent distribution of FTE scientists by ecoregions](chart.png)

*Source: Jha, Dayanatha and S. K. Pandey (2005), Research Resource Allocation*

2.8.6 Considering rationality, simple congruence analysis revealed that research resources were broadly allocated in accordance with relative economic importance of commodities. This is what one expects in a mature public system. Knowledgeable scientists and consultative processes lead to this. High congruity index values were obtained with respect to individual commodity groups as well. Condiment and spices was the only group which recorded low index value. Institution–wise assessment VOP and FTE ranking revealed that ICAR and SAUs had high correlations implying that research resources were well aligned, but for ‘other’ public institutions and private R&D, the two were not in accord.
2.8.7 A scoring approach incorporating efficiency, equity, sustainability, and trade/value addition showed the need for marginal adjustments between commodities. It suggested marginal increase in resources allocated for cereals, vegetables, commercial crops, livestock, and condiments/spices groups and withdrawal from pulses, tubers, oilseeds, fibres, plantation crops, and medicinal/aromatic groups. We note that such readjustment proposals are naive and should not be accepted at face value. Research resources allocation decisions are complex and these data and analyses only help in improving the information base for decision making.

2.9.0 Scientific Productivity and Research Impacts

2.9.1 Creation of new knowledge and its application to enhance social welfare are basic measures of effectiveness of a research system. Several indicators are used by analyst to assess this effectiveness. These indicators assess the performance in terms of development of intermediate research products, usable technologies, and their spread and impacts. For agricultural research, which is applied in nature, scientific publications and technologies are the two main outputs. These research outputs also adequately capture other research contributions like development of research methodologies and intermediate products, which either get published in scientific journals, or facilitate technology development.\(^1\) This section examines the trends in these main outputs of the ICAR-SAU system. Brief summary measures to quantify the socio-economic impacts are also discussed.

Research Publications

2.9.2 Research publications include journal articles, books and book chapters, monographs, research and teaching manuals, extension materials, etc. Since consistent time-series data are not available for all of these indicators, research articles indexed by three abstracting sources for agricultural and allied sciences are considered. These are the Science Citation Index (SCI), the CAB Abstracts (CABA), and the Indian Science Abstracts (ISA). Total number of research publications authored by the scientists working

---

\(^1\) Patent is another indicator of research product, but this was not considered due to lack of information and emphasis in the system.
in ICAR institutes and SAUs were taken from these three sources. There is a drastic decline in the number of the SCI-indexed publications in 1990 over that in 1980. This decline is deeper for SAUs and it continued even in 2002. ICAR institutes however showed a moderate recovery in 2002. What is more worrisome is that even the institutes and universities with better publication record could not achieve the 1980 level in 2002 (Table 20). This clearly shows depletion of upstream or strategic research in the ICAR and SAU system.

<sup>a</sup> SCI data are triennium averages; <sup>b</sup> Full-time equivalent (e.g., a scientist spending 50% of his time on research was considered as 0.5 FTE). Source: Pal, Suresh, 2005, NCAP, New Delhi

2.9.3 A sharp decline in the SCI-indexed articles authored by the agricultural scientists echoes the broad trend observed for the Indian science. The total number of SCI-indexed research articles authored by Indian scientists in all fields of science decreased from 14,983 in 1980 to 10,103 in 1990, but rose back to 14,028 in 2002. However, part of the slow recovery of the articles of agricultural sciences during 1990s
could be attributed to a shift towards publication in Indian journals which increased in number over time. These Indian journals were also rated high by the national professional academies and assessment boards.

2.9.4 Trends in the total number of publications of agricultural science are quite encouraging. The number of CABA-indexed publications of the ICAR-SAU system increased from 3,014 in 1980 to 6,058 in 1990, which further rose moderately to 6,664 in 1998. A similar trend was also observed for the ISA-indexed publications. This increase in the number of publications during 1990s is important because the number of agricultural scientists has gone down during this period. The number of publications per scientist per year also increased from 0.48 in 1990 to 0.51 in 1998, registering an increase of about 6 percent (Table 20). This clearly shows an upward trend in scientific productivity of the ICAR-SAU system. However, there are some noteworthy patterns. Nearly 80 percent of the papers were published in the non-SCI journals with zero impact factor and only a small proportion of the papers were published in the journals with an impact factor greater than zero but less than two. About half of the SCI-indexed and more than 70 percent of the total publications were authored by the scientists working in SAUs, which is expected because of their scientific strength and dominance of student research. However, the tendency to publish in the low rating journals is a matter of concern. The average impact factor even for the ICAR articles was 1.1 in 2002, as against 1.6 for CSIR articles, underscoring the need for improving the quality of agricultural science publications in the country.

2.9.5 Given the international norm of two papers per scientist in a year, the current productivity level (0.5 paper) of agricultural research is too low in India. The question now arises how can it be increased? Scientific productivity is directly related with the availability of research resources, both manpower and financial. It is found that an institute with higher budget per scientist is likely to be more productive than a poorly funded institute. At the same time, it is also important how the available resources are used. The institutes with higher proportion of operational expenses in the

---

2 Increase in the ISA-indexed articles is sharper due to widening of its coverage of publication sources.
3 The impact factor is the frequency with which an average article from a journal is cited in a particular year.
total expenditure and greater scientific interactions and institutional linkages are likely to have better publication record. In addition, age of an institute capturing institutional factors like history and culture of an organization has a positive impact on the publication efficiency. This is because of the fact that the accumulating stock of tacit knowledge and tradition of “good practices” help in efficient use of research resources and attracting best brains. On the other hand, a high proportion of top cadre scientists are associated with lower scientific productivity. These results have strong implications for the ICAR-SAU system which is dominated by the top cadre scientists. Also, the share of operational expenses in some of the institutions was less than 20%. Thus, balancing the cadre strength and factor-shares in research expenditure are essential for increasing scientific productivity of the system.

Technology–led Enhanced Productivity, Profitability and Sustainability

2.9.6 The number of usable technologies developed is another indicator of scientific productivity, for which time-series data are not readily available. Studies in this area, however, provide useful insights; for example, there is an upward trend in the number of varieties developed for rice - an important crop receiving greater research attention. During the 1970s, 127 rice varieties were released, which rose to 223 in the 1980s — almost doubling the breeding productivity. Part of this jump in the productivity could be attributed to increase in the number of rice breeders. The number of officially released varieties increased to 257 during the 1990s. Besides increase in the number of varieties bred, rice breeding also witnessed some qualitative changes over time. The proportion of varieties with fine quality (long slender) grain increased from 29% in 1970s to 36% in 1990s. Also, there is significant increase in the number of varieties developed for marginal production environments, as well as those tolerant to biotic stresses. This development has contributed to a substantial reduction in yield variability even in the rainfed areas of eastern India. Development of hybrid rice in partnership with the International Rice Research Institute and private seed companies have established yield advantage of 15-20%. Thus, maintaining high and stable yields with improved grain quality is a major contribution of Indian plant breeding programmes. Also, there was focus on breeding short duration rice varieties, which constituted about half of the total
varieties released during 1980s and 1990s. Fast expanding rice trade, especially of Basmati aromatic rices, is triggered by the modern Basmatis which are high yielding, disease and pest tolerant and as good or even better in aroma and quality when compared with traditional varieties.

2.9.7 Similar trends are also observed in breeding programmes for other crops. For example, in maize, the number of varieties (50) developed during 1980-1993 was higher than those developed (45) during 1960-1980. Also, there was a shift in breeding focus from varieties to hybrids during the 1980s. Recently, high protein maize hybrids are developed to meet the rising demand for food and feed. In the case of wheat, so far more than 200 varieties have been released for cultivation in India, and yield potential has been increasing by one percent per year due to the persistent improvement in plant type. Improvement in grain quality (for chapati making) and development of rust resistant varieties are the other significant contributions of the wheat breeding programmes. After the mid-nineties, an additional yield potential of about 0.7 tonne/ha has been established on farmers’ fields, which is likely to be enhanced further through exploitation of hybrid vigour in wheat breeding. The success of crop breeding programmes, coupled with the policy of open access to public material, has contributed rather significantly to the growth of private seed industry in the country.

Total Factor Productivity Growth and Rates of Return

2.9.8 Scientific contributions of the Indian agricultural research system are periodically reviewed by various expert committees and government bodies at different levels, and sustenance of the funding indicates that the Central and State governments are convinced of positive contributions of agricultural research. This is evident from a number of technological revolutions, often referred to as ‘rainbow revolutions,’ ushered in different sectors of Indian agriculture. Socio-economic impacts of these revolutions have been assessed quantitatively by a number of studies done by the national and international organizations. It is shown that investment in agricultural R&D is a ‘win-win’ option as it is the largest contributor to agricultural total factor productivity (TFP), which in turn reduces rural poverty significantly. Although there are
considerable variations, the average rate of return to investment in agricultural research was about 70 percent with a median value more than 50 percent. These rates are very much comparable to those obtained internationally, covering both developed and developing countries (Figure 13). Furthermore, the marginal internal rate of return to research investment in India ranged from 57 to 59 percent since the green revolution era. This is against 35 percent rate of return realized for private agricultural R&D, and 45 percent for public agricultural extension.4

![Figure 13. Median International Rate of Returns (%) to Research Investment in India](image)

Source: Pal, Suresh, 2005, NCAP, NewDelhi

2.9.9 Concerns are expressed in some circles regarding the trend in the growth of TFP, which in a way reflects on effectiveness of NARS. Table 21 provides a summary of important studies measuring TFP growth in Indian agriculture. The TFP growth was rather lower in the Eastern and West-Central India during 1977-87, but it picked up later, and most of the crops grown in these regions showed an appreciable growth in their

---

4 The marginal internal rate of return to investment in irrigation ranged from 4 to 6 percent during the corresponding period.
TFPs. The growth in agricultural TFP is estimated to be 1.4 to 2.1 percent since 1980, which is equal to that observed for the crop sector during the green revolution period. However, deceleration in the TFP growth for crops is observed in the Indo-Gangetic Plains during the mid-1990s. This is certainly an undesirable trend, but it would be premature to entertain the deceleration hypothesis based on the data for few years. Moreover, there is no clear indication whether this deceleration is because of slow improvement in the technical efficiency—an important factor for growth in TFP, or technological regression. Thus, there is no clear evidence of decline in the socio-economic impact of public agricultural research in the country. In fact, deceleration in the agricultural growth since the mid-nineties underscores the need for acceleration of technology flow to farmers, requiring higher investment in research and extension.

Agricultural Diversification

2.9.10 In horticulture, forestry and medicinal and aromatic plants, rapid multiplication of disease-free planting material by tissue culture is contributing to rapid adoption of improved varieties and higher crop yields. Availability of improved varieties and hybrids and better crop and pest management techniques have enhanced vegetable yields significantly, and the country is now the second largest producer of vegetables in the world. In the case of livestock, cross breeding and nutrition and disease management research have increased milk and meat yields and reduced mortality rates. But, the success was confined to dairy, commercial poultry and fish sector only, and subsistence livestock sector suffered because of limited commercialization of technologies which are often capital intensive, causing a scale bias.

Sustainability of Production Systems

2.9.11 The Indian research programme has also focused its efforts on improving resource-use efficiency, conserving natural resources, particularly soil and water, and rehabilitating degraded soils. The management of degraded lands posed an important challenge. Land degradation in the form of soil erosion, salinity/alkalinity, and waterlogging are posing serious threats to sustainable agricultural development. Research efforts made by ICAR and IARCs like ICRISAT have continued to overcome these problems. Watershed programmes have shown several benefits in various target domains, documented in the form of higher incomes, crop diversification, increase in irrigated area and fodder availability, and soil and water conservation. Controlling soil erosion was found to benefit sustainable agricultural production in rainfed areas. Vertisol technology was developed to overcome the problem of rainfed area. The benefits of adopting Vertisol technology were documented as easy cultivation, effective pest management, higher production, less labour time and cost, higher income, increase in food and fodder security, lower cost of seed and nutrients, better soil and water conservation, prevention of soil erosion, and effective use of rain water.

2.9.12 Sustainability-enhancing impacts are, however, not as visible as the impacts in terms of increase in crop yields. There is substantial reduction in waste and
unculturable land and area subject to water and wind erosion, and large tracts of saline and alkaline lands are reclaimed and brought under cultivation. Soil & water conservation technologies have reduced water run-off by 15 to 42 percent, controlling soil loss by 2 to 12 tonnes per ha per year. In addition, the watershed programmes have increased cropping intensity, on an average by 41 percent and created more than one hundred mandays of employment per hectare in a year. It is expected that the resource-conservation technologies like watershed development would reduce the use of groundwater for irrigation by 5 to 30 percent in the rice-wheat system. The packages for integrated management of pests and plant nutrients, along with pest tolerant varieties are expected to reduce the use of pesticides to the extent of 50 percent. Although there are some success stories showing tangible impacts of these knowledge-intensive technologies, a number of factors limit their spread, especially to small farmers. These are mostly group-based interventions and the system is still struggling to address the question of appropriate methodology and institutional arrangement for their dissemination. **Lack of adequate information, services, inputs and credit further restrict exploitation of improved technology by small farmers.**

**Benefits to Small Holders**

2.9.13 Has agricultural research in India also benefited small holders and unfavourable production environments like dryland areas? **Since the green revolution technologies in long term were generally neutral to scale, the growth benefits were also shared by small producers, and the urban poor benefited through reduction in food prices.** The high-yielding varieties also spread rapidly to dry semi-arid regions of the Central and Peninsular India and covered more than 74 percent of area under sorghum and pearl millet, which is higher than that of paddy. Of late, there is rapid spread of modern varieties in the eastern India, contributing to most of the increase in the national foodgrain production during the 1990s. **There is a huge potential of untapped yield enhancement in Eastern India.** Several studies have shown that technological change has been pervasive even in the rainfed areas, and crops like coarse grains, pulses, oilseeds, fibres, and vegetables have registered a positive growth in the total factor productivity. However, the impact has been rather limited in a few States, viz. Bihar,
Madhya Pradesh, and Karnataka, partly because of incremental nature of technological advancements (unlike one-shot jump in irrigated areas), which are often eroded by erratic weather conditions. Barring these few limitations, the agricultural research system has been able to address the objective of sustainable agricultural development with social justice, and economic policy environment has helped in achieving this objective. Of course, international agricultural research community, mainly the CGIAR system, has been a useful ally in this endeavour and there have been many technology spillovers. But, these technology spillovers from the CGIAR system would not have been realized in the absence of the strong national system.

2.9.14 Agricultural research leading to the adoption of improved technology may reduce rural poverty in many ways. We must get away from the too simplistic internal rates of return based on adoption of high yielding varieties. **New approaches could include:**

- higher on-farm yields and productivity;
- higher net income of farmers;
- expansion of farm employment opportunities and higher wages;
- growth of non-farm activities;
- lower food prices;
- reduced vulnerability to crop and other risks; and
- empowerment of the poor and of their organizations.

2.9.15 The last item, empowerment, has gained increasing attention in recent years. Unless the poor have the power to participate in deciding which technology to use, they are unlikely to benefit from it. In other words, better farm technology will most benefit the farmers who are active partners in setting priorities of R&D. An analytical framework for approaching the above issues should cover the following:

- What is the probability that applied research will be successful, and hence, what is a desirable measure of successful research in an R&D continuum?
• How soon will the results be available for adoption, how widely applicable will the results be, and when will they be adopted by various groups and for how long?
• Once adopted, what is their contribution to productivity and incomes of different groups of people, especially smallholders?

2.10.0 Major Challenges

2.10.1 Significant progress was made in the past 40 years and must continue to be made in the coming years in raising food consumption levels, improving nutrition, and reducing poverty through agricultural transformation. The efforts, however, need to be redoubled to meet WFS target and MDG to halve the number of hungry people by 2015. India is way off track in achieving the MDG goals. Hunger cannot wait. Further, resource-poor farmers are under acute distress and are finding it difficult to liberate themselves from the complex traps of multi-layer debts, poverty, poor access to institutional support, high production risks, market failures and declining returns. Average productivity of our crops and farm animals is low and wide yield gaps exist for almost all crops and commodities. **Why science and technology have failed to alleviate, if not completely eliminate, the distresses?**

2.10.2 As the world is experiencing revolutions in biotechnology, information and communication technology, nanotechnology, space technology and business management systems, veritable divides, such as technology divide, gene-divide, digital divide, gender-divide, rich-poor divide, rural-urban divide are dangerously widening, and threatening peace. **While the country harnesses the uncommon potential of the uncommon opportunities, it is challenged with the daunting task of bridging and narrowing the various divides.** The Challenge before us is to build research and technology development capacities and partnerships which will contribute to and capture the impact of Gene Revolution and other scientific revolutions. How can the national and international systems be strengthened to rationally manage biosecurity and TBT and minimize the adverse impacts of TRIPS and other WTO agreements on the small-scale farmers and fisherfolks and the poor and convert these provisions into an opportunity?
Bridges must be build across science, society and humanity so as to effectively share the
global knowledge and technology pool for more equitable and inclusive development.

2.10.3 The agriculture led broad-based economic growth must take place
under the settings where the natural base of production resources, such as land,
water and biodiversity, has shrunk, the biotic and abiotic stresses have intensified
and there is widespread environmental and agro-ecological deterioration. The
degradation of breadbaskets, such as the fatigued rice-wheat lands, irresponsible fishing
and aquaculture and industrialization of livestock production, stubbornly high post-
harvest losses, and disconnects among production, processing and marketing are
constraining the sustained accelerated economic growth that is needed to reduce poverty
and enhance food security. Moreover, climatic change, variability and global warming
and their impact on agriculture and vice versa emerge as new threats and management of
these changes resulting in minimization of the damaging agricultural trends is a real
challenge.

2.10.4 The precise causes of the agrarian crisis and waning of the Green
Revolution process are many and varied, but there are five basic factors which are
central to the present crisis. These are: unfinished agenda in land reforms; quantity
and quality of water; technology fatigue; access, adequacy and timeliness of
institutional credit; and opportunities for assured and remunerative marketing.
The disconnect between science and public policy, the decline in quality of agricultural
produce as well as no connectivity with the clients of farm research and adverse
meteorological factors add to these problems. The worst affected are the majority of
small and marginal farmers, tenants and share croppers, landless agricultural labour and
tribal farmers, since their coping capacity is very limited. Women suffer more since they
have little access to institutional credit or organized extension support.

2.11.0 The Road Ahead: Meeting the Challenges

2.11.1 Science and technology will be pivotal to the country’s effort to meet the
challenges enumerated above and to help our farm and fisher families to enhance the
productivity, profitability, sustainability and equity. For this the Commission
recommends a three pronged approach: **Firstly, we must prioritise strategic research and technology development programmes**, including cutting-edge technologies, geared to meet the technological problems retarding and decelerating agriculture-led growth and development. **Secondly, we must realize that science and technologies should have a human face and cannot operate in a vacuum.** Therefore, it is absolutely necessary to formulate clear cut goals, policies, strategies and programmes and build partnerships for harnessing the (unlimited) power of science and synergizing technological and social revolutions. **Thirdly, the National Agricultural Research System, the technology assessment and transfer system, the knowledge system (skill development, re-tooling, indigenous knowledge, the humanware aspects, enabling mechanism (IPR, SPS) and services must be synergistically aligned, restructured and revitalized to dismantle the unholy alliance of hunger, poverty, unemployment, unsustainability and exclusion.** In this context, the following aspects must particularly be addressed.

- Evolve a **national innovation system**—align policy, incentives and institutions in this direction
- Balance the roles of the Centre, States, corporate and rural knowledge centres in provision of R&D services
- Use critical scientific and modern management tools essential for viability and efficiency of public R&D
- Align external assistance with the long-term capacity building — human resource development, particularly in frontier and strategic research
- Manage IPRs for technology transfer and resource generation by becoming dominant technology provider in the South

### 2.11. A. 0 Priority Research and Technology Development Areas

2.11. A.1 Science and technology must address (for crops, livestock, fisheries and forestry) the following four interrelated areas in order to attain higher productivity and sustainability and thereby help alleviate hunger and poverty:
• Enhancing yield ceilings, bridging yield gaps, protecting yield gains, minimizing post-harvest losses, augmenting value addition and improving productivity and promoting ecotechnologies rooted in the principles of ecology, economics, equity and employment;

• Exploiting the gene revolution (biotechnology), benefiting from information and communication technology revolution, space, nuclear and nanotechnologies and promoting knowledge-based farming systems, precision agriculture, intensification, diversification and value addition;

• Protecting and improving natural resources (land, water and biodiversity), addressing environmental concerns, and managing climate change and natural disasters; and

• Seeking congruence of productivity, profitability, sustainability and equity, addressing gender issues and problems of poor and the excluded, and managing liberalized trade in the globalised world by addressing issues related to global competitiveness in the context of the WTO AoA.

2.11. A.2 **In undertaking the above programmes, we must realise that basic (fundamental), strategic and applied researches constitute a continuum and are mutually reinforcing.** The Indian NARS has successfully been undertaking research in each of these categories. The modes of conducting researches have also evolved over the years. Lately, need for anticipatory and participatory researches have been felt to fill the gaps not covered by the usual modes of generating and transferring technologies. Given the persisting yield gaps and widening income inequity on one hand, and the fast changing global technological and socio-economic scenarios on the other hand, India needs to give high priority to strategic, participatory and anticipatory researches. Climate change, sea-level rise (the Tsunami 2004 is a cruel reminder to unforeseen destructions) and other such events call for national preparedness to meet these emergencies and new challenges by instituting and strengthening anticipatory researches. Strategic research, such as genomics and proteomics, which is geared to problem-solving, will particularly be helpful in removing the critical bottlenecks in technology. Participatory approaches of technology designing, verification and refinement will greatly ensure quick and
comprehensive adoption of technologies developed through inter-disciplinary and system-based programmes. The Commission suggests the following strategic and anticipatory research areas for priority action:

**Breaking Yield Ceilings, Bridging Yield Gaps, and Protecting Yield Gains**

2.11.A.3 It is encouraging that yields of major crops have continued to increase during the past 35 years; they are projected to increase towards 2030, albeit at a decelerating rate, but nonetheless implying a continued need for developing the technologies wherewith to achieve increased yields. For instance, rice, central to the nation’s food security must maintain annual yield growth of about 2 percent towards the year 2020 to meet the demand. As cropping intensity becomes increasingly important, the features of crop duration and high per day productivity become preferred attributes.

2.11. A.4 As regards breaking yield ceilings, conventional breeding and management practices continue to offer great prospects of developing new super ideotypes, hybrids, and new life forms characterized by greatly enhanced new levels of yield, productivity, and adaptability, such as the **Super New Plant Type, Super Hybrid, aerobic and NERICA rices and extra-long-spikes, and hybrid wheat cultivars**. These will be complemented by various genetically engineered products. Quality, consumer preferences, cost effectiveness, and environmental aspects of production, distribution, and consumption of these new types will need to be critically analyzed in order to assess efficiency and efficacy of their large scale popularization in the broader context of food security, poverty alleviation, sustainability, equity and biosecurity.

2.11. A.5 As regards bridging yield gaps, **50 to 100 percent transferable yield gaps are not uncommon**. There are several agro-ecological and socio-economic causes for the gap in bridging the exploitable yield gaps. With increasing emphasis on precision agriculture, there are greater chances for narrowing the yield gaps. The existing exploitable yield gaps should be seen as an opportunity for future growth that is consistent with agro-ecological, environmental, socio-economic, political and technological settings in the major production regimes. With newly-improved methodologies for systems analysis, and greater access to relevant data, reliable estimates
of potential yields in specific agro-ecological regimes are increasingly available. Such estimates will assist in estimating more reliably the gaps between actual and potential yields, and will assist also in charting strategies to bridge yield gaps.

2.11. A.6  As regards protecting the yield gains, under certain production regimes there are signs of decline in actual yields. A long term strategy and a site-specific and knowledge-intensive soil-fertility orientation are needed for the fertilizer-use technology transfer, adoption and monitoring by the extension advisory system and the farmers themselves. **Soil-test based fertilizer application**, particularly micro nutrients, real-time nitrogen management by leaf chlorophyll meter or leaf colour chart and soil nutrient budgeting, will be the elements of precision agriculture to sustain high yields and lessen the inputs-related deceleration of partial factor productivity. This approach calls for a paradigm shift in the technology transfer approach, based on intensive knowledge and higher capacity of extension agents of both public and private sectors. A **consortium approach** involving scientists, grassroot institutions, corporate sector, NGOs, financial institutions and farmers is urgently needed.

**Soils**

2.11. A.7  Imbalanced agricultural intensification, excessive and unsustainable exploitation and consumerism-related industrialization under demographic pressure have over-drained our soils which have increasingly become both hungry and thirsty. Micro-nutrient deficiencies are spreading fast. These have caused **widespread decline in total and partial factor productivity growth rates** while demand for enhanced, sustained and pollution-free agricultural production is ever intensifying. **Enhancing input use efficiency and competitiveness must be our priority agenda.**

2.11. A.8  Classically, soil has so far been seen as a medium of plant growth to meet basic needs of humans and its other functions of regulating biosphere integrity and sustaining biodiversity have received scant attention. “**Soils don’t only serve for agriculture and forestry, but also for filtering, buffering and transformation activities between the atmosphere and the groundwater, protecting the food chain and drinking water against pollution and biodiversity.** Regarding the latter, soil is
the most important gene reserve, containing more biota in species diversity and quantity than all other aboveground biomass on the globe” (Blum, 2002, 17th World Soil Science Congress). Conceptual frameworks of development indicators generally ignore these vital functions of soil and need a re-look.

2.11. A.9 Soil organic matter (SOM) is the mainstay of soil quality. While balanced fertilization may meet crop productivity and maintain SOM, it is an urgent imperative to improve the sequestration of carbon in all the soils by all available means including recycling of crop residues, green manuring, composting, reduced tillage etc. We must realize that the “grains belong to humans but the residues belong to the soil”. So carbon sequestration should be an urgent priority, irrespective of its effect on climate change. Enhanced use of bio-fertilizers, soil microbes, bio-pesticides and bio-control of weeds may be given high priority.

2.11. A.10 Establish a National Network of Advanced Soil Testing Laboratories capable of testing large volumes of soil samples for 16 macro and micronutrients – 1000 laboratories in all parts of the country, to begin with. At least 500 of these should be located in dry farming areas where there is scope for doubling average yields immediately through addressing the deficiencies of micro-nutrients and the overall nutrient imbalance and deficiency in the soil. Revitalize and retool existing soil testing laboratories.

2.11. A.11 Provide each farm family with a Soil Health Card containing information on physical, chemical and microbiological profile and health of the soils. A dedicated cadre of soil technicians/scientists for the National Movement on Soil Health Care with defined targets and resources (functioning equipment and trained human resources at the soil testing laboratories) should be created.

2.11. A.12 Agri-clinics, Input Distribution Centres, Small Farmer Estates, Cooperatives, Block and District Level Science and Technology Consortia and Panchayat Raj Institutions must integrate their efforts for ensuring soil health in conjunction with integrated watershed development systems and the Technology Missions. Farmers must
be trained to follow the recommended practices. Special extension programmes based on large scale **participatory demonstrations** should be organized. KVKs, both for soil testing and training, must play a pivotal role in this work.

2.11. A.13 Fertilizer companies should be encouraged to produce, demonstrate and market new fertilizer combinations and mixes to promote balanced fertilization in a cost-effective and environment-friendly manner. **The revitalized Land Use Boards should be highly proactive in matching soils with most appropriate cropping and farming systems.**

2.11. A.14 Productivity of wastelands may be restored especially with inputs of social capital for removing poverty by enhancing self-employment, income generation and livelihood opportunities for small/marginal farmers and landless communities. The National Rural Employment Guarantee Scheme may particularly prove helpful in this resolve.

2.11. A.15 People must be made aware and sensitised of the shrinking capacity of soils to absorb any more abuse. A **National Soil Charter** structured on the “World Soil Charter of FAO” and “UN Soils Convention” should be created to ensure soil health security.

**Water**

2.11. A.16 Water, the life blood of agriculture, is under severe threat. Allocation of water to agriculture is facing a losing battle with the industrial, domestic, power and other sectors. There is also a compulsion to intensify agriculture under the constraints of declining per capita land and water availability. **The lack of water availability on the one hand and inefficient use of available water on the other have limited our agricultural production much below its potential.** Besides, there is a gradual deterioration in the quality of water. The adverse impact of expected climate change on precipitation, temperature and sea level rise as a consequence of global warming is no longer a theoretical conjecture and will further aggravate the precarious situation faced by Indian agriculture. It is therefore imperative that any technology and policy for enhancing
agricultural productivity must take into account the need for evolving programmes for efficient water management.

2.11. A.17 During this first year (2005) of the **UN Decade of Water for Life**, while India, under the Bharat Nirman Programme, has committed to add 10 million hectares over the next few years to its 56 million hectares already under irrigation (the highest in any one country of the world), top priority must be given to conserving every drop of water and rendering “**water as everyone’s business**” to ensure most judicious and efficient use of this most precious resource. Hydrological balance, water security and water-use policy, water users’ associations, storing water everywhere, recharging million wells, reviving dying wisdom for water conservation and use, energy and water pricing, integrated watershed management and convergence and synergy among missions comprise major water conservation and use initiatives.

2.11. A.18 **Precision agriculture** is a key to efficient water management. The concept of traditional agriculture is to be modernized to allow administering inputs and undertake farming operations precisely. This will need mutual collaboration among the scientists, the field functionaries and the farmers.

2.11. A.19 The much talked about **river linking programme** for inter-basin water transfer has taken a small step forward through the **Ken-Betwa** link canal. The consequent impact on productivity and more importantly the water and soil environment are only guessed at present. A systematic evaluation may be initiated to learn lessons from this programme and prepare us for undertaking similar and bigger endeavours in future.

2.11. A.20 Despite having a vast water management research database, **field-worthy information on certain important issues is yet to be generated**. These are on water management with mulches, on tuber crops, on system of rice intensification, its efficiency vis-à-vis land levelling index and sustainable methods of rainwater conservation and use.

2.11.A.21 Under monsoon climate, temporal and spatial deficits and excesses of water are common even in irrigated regions, as the source of water for the reservoirs is the
rainfall. This calls for supplementing the deterministic research results by considering the stochastic behaviour of rainfall, and hence, the water availability for agriculture.

2.11. A.22 A travelling workshop of experts from India and from the Nile, Jordan and Imperial Valleys should be organized to formulate new strategies for water management along the Rajasthan canal and other such existing and planned command areas. Water related tensions in rural areas are increasing. Timely and anticipatory actions must be taken to alleviate the conflicts.

2.11. A.23 Both the anthropogenic and natural causes of occurrence of poor quality water are known and their piece-meal solutions are also known. Looking into vast areas under such problems and their adverse impact on agricultural production, an ‘Integrated Water Use and Management System’ is to be developed to address the problem in a sustainable and holistic manner.

2.11. A.24 Bio-drainage is suitable for partially salvaging non-remunerative wastelands that are saline, waterlogged and abandoned. With some ingenuous planning, some normal cropping may be done along with plantation for bio-drainage in marginal lands. This will require evaluation of the environmental impact of bio-drainage and developing plantation geometry for selected tree species that are most suitable vis-à-vis the land and water quality. Despite successful demonstration of conventional land drainage technology, Indian farmers have not adopted or maintained them on their own. Like irrigation development, drainage development should also be considered as a national objective and given adequate departmental support.

2.11. A.25 Pressurized irrigation technology should be user-friendly, suitable also for small to marginal landholders and compatible with the available energy scenario in the countryside. The general awareness about the design criteria for pressurized irrigation system and its layout suiting to diverse field and horticultural crops and quality assurance are lacking among the manufacturers, suppliers field functionaries and farmers. Necessary steps, perhaps through a number of training programmes, should thus be taken to remove the aberration to benefit the users.
2.11. A.26 Remote sensing, simulation models, artificial neural network, GIS, geostatistical analysis etc., have great potential in water resource assessment and on-farm water management, and thus need to be applied for development and sustainable management of water resources. Application of modern tools to monitor ground and other water resources in relation to cropping pattern is required to diversify crops so as to prevent injudicious use of water resources.

2.11. A.27 National Water Policy should emphasise Integrated Water Management encompassing water harvesting, conservation, rehabilitation of waterbodies and ground water recharge. Efficient utilization of water must be considered as the core of a watershed development and management programme and such programmes are to be developed according to the ago-climatic environment of a region. Marketing facility is essential before going for diversification in agriculture using the harvested rainwater and such facilities need to be created simultaneously with the watershed development programme.

2.11. A.28 Mindset of all those who are associated with watershed programmes needs to be changed to consider water programmes not as merely departmental activities but as saviours of the rainfed agriculture and all who are dependent on it. This may be attempted through awareness generation programmes. Participatory Irrigation Management (PIM) is essential in irrigated regions to ensure sustainability of water use with high efficiency. Technology transfer procedures must find place at local levels and a mandatory mechanism needs to be developed involving farmers, administrators and the research institutions.

2.11. A.29 A National Research Centre on Glacierology should be established for collection, storage and dissemination of information on status of seasonal/perennial snow and ice. The Centre should undertake research on understanding the interaction amongst biological processes, physical environment and the climate change and develop early, medium and long-term warning systems and advise on trends of water availability and overall hydrological situation in the medium and long-term.
**Biodiversity**

2.11. A.30 Biodiversity, comprising genetic resources, is the building block of functions and forms of living organisms and will always be needed to produce new genotypes to meet the ever changing needs of humankind. New sciences of biotechnology and bioinformatics, coupled with conventional sciences, should be judiciously used for developing efficient and effective methods of conservation, utilization and exchange of genetic resources. Due to economic and population pressures the resources are eroding fast. Moreover, their availability is getting increasingly restricted due to their propriety protection under several systems. The Cartagena protocol for conservation, biosafety and sharing of genetic resources provides largely accepted and harmonized current practices and standards, and should be accepted by all countries. Along with Plant Breeders Rights, Farmers' Rights should be honoured and implemented for equitable and fair sharing of genetic resources. In this context, the indigenous rights over genetic knowledge and women's sphere of plant knowledge should be recognised under any intellectual property rights regime. The PVPFR Authority should ensure strengthening of national biodiversity management capacity implementation of the Farmers’ Rights and execution of the TRIPS and SPS commitments.

**Livestock**

2.11. A.31 *Livestock, whose ownership is more egalitarian as compared to land, is emerging as a driving force in the growth of agricultural sector of India.* Contribution of livestock to Agricultural Gross Domestic Product (AgGDP) has increased from 14% in 1980-81 to 26% in 2000-02. Demand for livestock products is income elastic and sustained growth in per capita income of the population, rising urban population, change in food habit are going to fuel further growth of this sub-sector. More than equity and balance, the rural livestock provides sustainability to the total agricultural operations. In spite of poor infrastructure, low investments and low priority shown to this sub-sector, livestock has provided sustainability and stability to agricultural production. The greatest contribution from livestock in the current concept of global economy and the national agriculture resurgence is in terms of sustainability to the total rural development,
which the livestock only can provide, especially to the landless agricultural workers and marginal farmers.

2.11. A.32 But, research and technology development supports for the livestock subsector have been neglected. Besides low productivity, poor nutrition and fodder and feed availability, poor health and high incidence of diseases and highly disorganized breeding and germplasm conservation programmes have serious depressing effect on the industry. Bluetongue, Bird Flu and other highly contagious diseases must be contained and eradicated and not allowed to enter the country. Thanks to the NDDB that the dairy sector, due to production-processing-distribution linkage with an end-to-end approach, has rendered India as the foremost milk producing country in the world. Such an approach must be popularized widely.

2.11. A.33 For enhancing the role of livestock for livelihood security, the following actions are required:

- Set up a Livestock Feed Corporation of India to provide support to local level SHGs engaged in the production of fodder and feed and in organizing Fodder and Feed Banks. Strengthen applied research in different agro-ecological regions so that livestock owners can implement correct feeding regimes using locally available feedstuffs and roughages. Research on ‘rangeland management’ on private and govt.-owned wastelands and rangelands is needed to increase production and availability of grasses for small grazing ruminants such as sheep and goats. This research should aim to increase the productivity of these land resources using low input technology although initial establishment costs are likely to be comparatively high. There is need for research on economic feeding systems for increasing slaughter weights of lambs and kids.

- In the case of poultry production, Poultry Estates may be organized with the help from the National Egg Coordination Committee and the organized poultry industry to help SC/ST and other resource poor communities take to economically viable poultry farming. Poultry Credit Card (as also Dairy Credit Card) should be issued to promote entrepreneurships.
Quarantine arrangements may be strengthened to **avoid the outbreak of epidemics caused by invasive alien species.** Poultry farming should be regarded as an agricultural enterprise and should be given special attention from the point of view of biosecurity.

Promote institutions and establish mechanisms to ensure **quality consciousness in milk, meat, vaccine and other products of this sector.** Encourage research and innovation to enhance sector level efficiency in quality production, value addition, procurement, processing, storage and marketing of all livestock products, including those based on small ruminants.

The government should encourage systematic area specific animal disease control programmes on the basis of a co-ordinated national plan under the overall guidance of the National Advisory Committee. The government should also structure, under a **National Animal Production and Health Information System (NAPHIS)** in the Central Department of AH&D, a dynamic disease information reporting and feedback arrangement. Special attention should be paid to Bluetongue and Avian Flu.

A **national livestock breeding strategy** needs to be evolved to meet the requirements of milk, meat, egg and other livestock products and their distribution. Major thrust should be on genetic up-gradation of indigenous/native cattle and buffaloes using proven semen and high quality pedigreed bulls and by expanding artificial insemination network to provide services at the farmer's level.

Research needs to be done on appropriate breeding objectives for indigenous breeds and appropriate methodology for implementing breeding programmes. This should especially include formulation of selection indices and accurate genetic evaluation to ensure steady genetic progress.

**Conserving Genetic Heritage and Harnessing Unique Niches:** The national bureau of animal genetic resources should chronicle and digitise inventories of the livestock genetic resources and associated traditional knowledge, and launch gene literacy movements to sensitise all stakeholders. The Suratgarh Farm (Rajasthan)
and other such farms of the Government of India should be developed as an *ex situ* germplasm repository of livestock genetic resources.

**Climate Change, Risk Management, Disaster Mitigation and Environmental Protection**

2.11. A.34 We have just past the first anniversary of the tragic Tsunami which on December 26, 2004 swept countries bordering the Indian Ocean that claimed the lives of more than 280,000 people and displaced 1.5 million people from their homes. Fisheries and coastal agriculture were severely damaged. In India, 300,000 fishers were made jobless. Furthermore, productive lands have been lost due to massive erosion and salinity infusion.

2.11. A.35 The Indian Ocean tsunami is one in a series of recent powerful natural disasters affecting developed and developing countries – from unexpected occurrences like earthquakes, floods, and cyclones to less immediate and evolving hazards like droughts and environmental degradation. The October 2005 South Asia Earthquake affecting Pakistan and India has resulted thus far in about 75,000 human casualties, and about $330 million loss in livestock, crops and agricultural equipment as estimated by ADB/World Bank. The trend in the past two decades shows an increase in both the number of natural disasters and the number of people killed by them (Figure 14). In the past two years, the number of deaths from natural disasters has been far above the past decade’s average.

2.11. A.36 In India, natural disasters such as floods, droughts, earthquakes, landslides and cyclones are of frequent occurrence and cause colossal loss of human lives, damage to properties and loss of crops. While most of the disasters are natural, some are aggravated by man-made activities. Need to develop strategies for disaster mitigation by agriculturists was never felt greater than today. To feed the ever increasing population it is essential to counter the adverse impacts of disasters in order to save and enhance the agricultural production. While doing so, care must be taken to prevent over exploitation and degradation of resources, which are to be maintained for the future generation. Natural resource management plays a key role not only in improving the land and water
degradation during crop production but also in protecting the environmental quality. Concerns for environmental pollution, especially from soil inputs to increase production have led the scientists to focus on the processes and procedures which can maintain land sustainability, arrest the processes of land and water quality deterioration and accelerate the rate of restoration of any natural resource. Approaches based on physical, chemical, biological and socio-economic principles can be most effective in providing solutions for mitigating disaster adversities, conserving resource base along with least detrimental influence on environment.

![Figure 14. Lives Lost to and Number of Natural Disasters, 1990-25](image)

**Source:** EM-DAT 2005

2.11. A.37 Global warming and the resulting climate change are likely to have adverse impact on India’s water resources, agriculture, forests, industries, energy and transport, human health and coastal zones. **Rising temperatures are expected to result in the reduction of the country’s wheat and rice yields in the next two decades.** By affecting agriculture and forestry, global warming is likely to jeopardize livelihoods and food security by drying up river basins. The major impact of climate change is abnormal changes in weather patterns, which are already being felt. Erratic rainfall patterns are going to disrupt the management practices for crop production. Most countries in temperate and tropical Asia including India are experiencing occurrences of extreme weathers like droughts and floods. The global warming is threatening the melting of ice...
and glaciaces. This is going to cause rising of sea levels thereby exposing the low-lying coastal areas to severe environmental stresses.

2.11.A.38 About 30 per cent geographical area (32 m ha) in arid zone are prone to drought and famine. Rainfall deficit, delayed arrival of mansoon, early withdrawal, large gaps in between rainfall events in eastern India, Jharkhand, Chattisgarh, M.P. etc. are the main causes of agricultural droughts causing damage to crops and bringing miseries to farmers. On the other hand, the excess rainfall causing floods, damages the standing crops in fields, erodes the fertile soil from croplands and makes transportation of produce extremely difficult. Occurrences of earthquakes, cyclones, avalanche, landslides and tsunami create destruction in all forms whether houses, buildings, crops, properties or most importantly humans lives.

2.11.A.39 There is rapid advancement in the development of the modern tools like remote sensing (RS), geographic information system (GIS), global positioning system (GPS), simulation modeling and information technology. The combination of these technologies provide a cost effective means of acquiring high resolution real time data through RS, data management and analysis through GIS, georeferencing the ground truth data with GPS and utilization of data for specific purpose and management through simulation modelling. Thus, these can serve as very useful tools for precise assessment and sustainable development. The following areas deserve greater research attention:

- The isotopic ratio of Helium in ground water is a sensitive index for tectonic plate activity below earth’s crust. Regular mapping of isotopic Helium concentrations in groundwater around the known tectonic fault lines and well-demarcated earthquake prone areas, can provide early forewarning signals for timely remedial action on the part of local administration. Further investigations on these aspects are recommended.
- Development of various kinds of early warning systems is required.
- To combat desertification, more research should be focused on non-nucleating theory of raindrop formation, which may explain cloud formation more scientifically than nucleating theory.
The geophysical factors of an area, which are primarily responsible for desertification, need more attention and study than the climatic factors.

Ozone is the most important air pollutant in terms of damage to crop plants and also injurious to human health.

Studies should be initiated for monitoring of earth surface ozone levels in India.

The effects of changing/increasing levels of ozone on crop growth and yield should be studied.

Precision in climate change prediction must be higher for temporal and spatial scale resolution.

The bio-physical and socio-economic aspects should be linked with climate change for realistic estimates of agricultural impacts.

Bio-physical traits such as leaf membrane stability index, canopy temperature depression and spin lattice relaxation time may be explored to be used as selection criterion for adaptation to temperature stress in wheat.

There is need for providing accurate advanced information on weather and its possible implications on the standing crops to farmers.

Adequate precision is required in predicting the short term high temperature conditions or heat wave conditions which are likely to damage agricultural crops.

Thermal time concept may be a useful tool in forewarning mustard aphid a month in advance.

**Bilateral collaboration with selected institutes abroad, especially nanotechnology-based work in USA, will be extremely helpful in the above areas.**

**Greening the Grey Areas: Accent on Rainfed Drylands**

2.11.A.40 Rainfed and other less favoured areas have the highest concentration of poor and malnourished people; these highly risk prone areas are characterized by low agricultural productivity, high natural resource degradation, limited access to infrastructure and markets, and other socio-economic constraints. In the interests both of improving household food security and lessening socio-economic inequity, and also of
raising national agricultural production, research and technology development must give greater attention to soil health, water conservation, livestock for livelihood security, horticulture and agroforestry in the rainfed areas, while maintaining and further increasing the gains made in irrigated areas. Genetic improvement for tolerance to water stresses (both scarce and excessive), salinity, acidity and other abiotic stresses as well as to biotic stresses, water harvesting and enhanced water and fertilizer use efficiency, management of soil erosion, crop-livestock integrated farming systems, participatory research, contingency farming and agro forestry should be high priority research agendas in rainfed areas. Technology transfer systems, including input and institutional supports should emphasize precision and pace, hence the need for greater skill alertness and commitment.

2.11.A.41 Yield and productivity gaps are particularly large in rainfed areas. This is attributed mainly to large variability of soil features, negligible control on water, weak technology assessment, refinement and diffusion mechanisms and poor institutional supports. Nonetheless, there are several successful stories of bridging the gaps at various levels, which should be critically analysed for identifying the underlying drivers of change and their judicious scaling up and adoption for greening the grey areas. A recent IFPRI study had examined the prospects of replicating and sustaining sporadic and isolated instances of technology-triggered success stories of enhanced yields to achieve broad-based aggregate successful growth in rainfed agriculture and suggests that, “where there is participation and individual motivation, where incentives are aligned with improved means to respond to incentives, and where technology plays a pivotal role, success may follow”.

Managing the Gene Revolution

2.11.A.42 The global area planted with biotech (GMO) crops has steadily increased during the last nine years. Today, about 9 million farmers in 17 countries are growing such crops covering about 85 million ha. India, so far, grows only one biotech product, i.e., Bt Cotton, occupying nearly 0.5 million ha under legally-released Bt hybrid varieties and an additional about 0.5 million ha under “illegal” Bt hybrid varieties. A recent study
reveals that, on an average, 30 percent of the illegal seeds are non-Bt, only 27 percent are F₁, rest of 43 percent are only 10-75 percent positive for Bt, indicating F₂ and mixtures. Fake cartons of the legal seeds are increasing.

2.11. A.43 The parallel production of legal and illegal biotech varieties underscores the strengths as well as weaknesses of the technology. The strengths encompass higher resistance to bollworms (a serious cotton pest) – significantly reducing the number of pesticide spray and the amount of pesticides used, thus cutting down both cost and environmental pollution. Higher yield, superior quality and early maturity are other benefits of Bt cotton varieties. The weaknesses include greater chances of corruption of seed chain, high seed cost and greater chances of non-adherence to the biosafety measures, viz, non-growing of refugia. Bt detection kits are available and should be used judiciously and transparently to confirm truthfulness of the seed and to build up quality control and faith of the farmer in the technology and the seed chain. The research and regulatory and extension systems must be effectively aligned to ensure smooth and cost-effective flow of quality seed.

2.11. A.44 The Gene Revolution is primarily propelled by the private sector. This paradigm shift has important implications for the kind of research performed, types of technologies developed and the way the technologies are disseminated. It raises concerns that the small farmers may not benefit. As per our needs, prospects and capacity, India should develop dynamic policy on biotechnology which must map out ways to benefit all stakeholders, especially small farmers, and minimize negative effects, if any.

2.11. A.45 The potential of biotechnology should be approached with a balanced perspective by integrating it within the national research technology and development framework and using it as an adjunct to and not as a substitute for conventional technologies in solving problems identified through national priority setting mechanisms. Priority setting should also take into account national development policies, private sector interests, market possibilities, potential for adoption by farmers, public perceptions of safety, and consumers' views. Accordingly, various stakeholders, public sector, private
sector, industries, NGOs and wider segment of civil societies should be involved in the formulation and implementation of national biotechnology policies, strategies, plans and programmes.

2.11. A.46 A panel chaired by M.S. Swaminathan, June 2004, had prepared a National Biotechnology Policy document and suggested the establishment of an autonomous National Biotechnology Regulatory Authority to oversee and harmonise biotechnological developments in fields of Agriculture and Food, Environment and Medicine and Pharmaceutics. The Department of Biotechnology has also been preparing a document on national policy on biotechnology through a widespread consultative process. The National Commission on Farmers considered these two initiatives and widened the scope of the consultative process by organising a consultation with farmers and farmers’ organisations, September 2005. The consultation suggested that National Policy on Biotechnology must address the following issues: (i) value, usefulness and appropriateness of biotechnologies, (ii) risk and biosafety aspects and their management, (iii) equity and ethical dimensions, overall awareness and promotion of pro-poor features of biotechnologies, gene literacy, (iv) control of and access to biotechnologies, the role of public and private sectors, harmonization of various regulatory provisions, and (v) investment in research and other institutional supports and partnerships for transparent and balanced harnessing of biotechnologies. It had emphasised that Pro-poor features of biotechnology should be judiciously harnessed to attack directly the issues of food insecurity, malnutrition, and poverty.

2.11. A.47 The National Commission on Farmers’ Consultation had endorsed the establishment of the above mentioned Authority as also of a National Biosecurity Institute steered by an Advisory Committee comprising scientists, representatives of public and private sectors, industry, CSOs, NGOs and farmers. The consultation had recommended that the Authority should combine both regulatory and advisory responsibilities and coordinate and harmonise the various socio-economic and other development aspects, regulatory measures and bioethical and biosecurity norms towards harnessing biotechnologies for the good of the common man (Aam Aadmi).
Diversification

2.11. A.48 Science and technology development has been the main force in enlarging people’s choice both by expanding human capacities to harness technologies and by providing menu of products to meet fast-changing needs and demands of humankind. There are several excellent examples of science and technology led diversifications such as the rice-wheat system, conservation farming, aquaculture and horticultural revolution. Diversification will be successful only if it:

- Responds to market changes, trade liberalization, shifts in food habits and food baskets and to other socio-economic developments and agro-ecological settings;
- Increases employment/income-generation opportunities and judicious use of land, water, labour, biodiversity and other resources;
- Reduces the incidence and damage caused by pests and diseases and risk diffusion leading to higher and more stable production and income; and
- Promotes resource conservation through the adoption of integrated farming systems (incorporating integrated pest management and integrated plant nutrient management), thereby exploiting synergism and lessening the requirements for and reducing the pressure on increasingly scarce water, land, and other resources.

2.11. A.49 To realize the fore-listed possibilities, policy guidance and institutional supports must be in place to induce appropriate technology development. Technologies suitable for integrated crop-livestock farming, especially for small-holders, should have priority for development and diffusion. Moreover, the production systems, including organic agriculture, should be linked to effective markets to increase farm income and poverty reduction.

Value Addition and Prevention of Post Harvest Losses

2.11. A.50 Post harvest losses, on an average ranging from 10 to 30 percent depending on commodities, being high in horticulture, livestock and fisheries - all high value products, are colossal. For instance, in horticulture, serious mismatch between production and consumption continues although there is no reliable data
available to estimate the success achieved during the last 10 years in reducing post harvest losses. The estimates of monetary losses being incurred in the country keep rising at regular intervals, as evident from the four reports brought out during the past decade: 1993-94 = Rs 8,000 crore (Min. of Food Proc.); 1996-97 = Rs. 25,000 crore (Mckinsey Report); 1999-00 = Rs. 50,000 crore (Anon.) and 2004-05 = Rs. 85,000 crore (Direcotrate of Marketing, Maharashtra). The huge investments made not only by the Department of Agriculture and Cooperation, but also by the APEDA, NCDC, NAFED, Ministry of Food Processing etc. have thus not succeeded much in reducing the staggering post harvest losses. No authentic data are available on the reduction in losses, if any, achieved due to the infrastructure created, improved PHM technologies promoted and several policy initiatives taken for streamlining the systems involved. All investments and efforts made for improving PHM have ended at the storage level of bulk quantities of a few commodities, with no care taken at the retail level. Consequently, the fresh produce continues to be sold in open stalls, roadside kiosks, carts, footpaths etc. causing serious loss in quality of the produce besides adding to the PH losses.

2.11. A.51 Further, liberalization has brought focus on technology as a major factor in competitive marketing, which should be duly reflected in new agriculture and science and technology policies. As trade shifts from primary products towards processed and manufactured products, greater emphasis will be needed for agroprocessing and post-harvest technologies that convert primary products into quality products and value-added products. Horizontal and vertical diversification can together proceed to expand options for quality products that meet fast-changing demands of local and foreign markets. Trade - , biosafety - , gene - and legal-literacy should be ensured at all levels, from farmers to policy-makers. These moves will promote farmer-industry linkage, small and medium enterprises (SMEs), rural entrepreneurship, and off-farm rural employment. It will be necessary to create marketing infrastructures that pay increased attention to food safety (as by cold chains) and to minimize post-harvest losses - particularly large for horticultural, livestock, and fish products. Institutional innovations will have to be explored, e.g. Contract Farming, Nucleus-Estate linkage systems, Small Holders’ Estates and Futures Markets. The group dynamics will promote
decentralized mass production by masses and benefit from centralized services. Through ensuring backward-forward linkages under an end-to-end approach, the Small Holders’ Estates will synergise production-processing-marketing linkage.

2.11. A.52 Efforts are underway in different countries to identify specialty commodities, such as off-season varieties and production systems, new crops, and novel varieties and breeds to capture new opportunities. With the increasing demand for herbal medicines and botanicals, and for organically produced food, aquaculture and other products, several countries have developed specific production and distribution patterns. Public and private sector support in supplying quality seed, planting materials, processing, procurement and marketing to promote these initiatives is a condition sine qua non. Individual countries have developed or are developing policies, strategies and programmes on such diversifications. As several of these initiatives are innovative and diverse, there is good scope for sharing such experiences through information system networks as well as through Technical Cooperation among Developing Countries (TCDC) arrangements promoted by FAO and other UN agencies and international organisations.

Aligning R&D to Manage WTO AoA

2.11. A.53 The share of agricultural trade in total agricultural GDP of the country had increased to nearly 10 percent during the TE 2004 from 6.3 percent during the TE 1995. The WTO AoA provides both opportunities and threats to agricultural families and agro-based industries. It was hoped that the trade liberalization will help accelerate the agricultural export leading to high net trade and will be instrumental in improving efficiency in allocation of resources. As seen from Table 22, in the post-WTO era, both export and import have increased substantially. However, the increase in imports was relatively higher than that in export, thus bringing down the proportion of surplus to GDP from 3.2 percent in TE 1995 to 2.7 percent in TE 2004, although there was a hump in the initial post-WTO years. This trend has adversely affected our self-reliance in agriculture. The value of export required to financing imports increased from 32 percent in the pre-WTO era to 57 percent in the post-WTO era.

Source: Chand, Ramesh, 2005. WTO and Indian Agriculture: Issues and Experience

2.11.A.54 Export of marine, livestock and horticultural products maintained the tempo of growth continuing from pre-WTO period whereas there was a setback to the exports of oilmeal and the earnings from traditional groups consisting of tea, coffee, spices, etc. declined sharply. Primarily caused by declining international prices, imports of several commodities increased substantially, at times hurting domestic production of major crops and the country was not able to safeguard interest of the farmer-producer. Vegetable oils accounted for more than three-fourths of the total increment of agricultural import in post-WTO era. Imports of pulses, spices, cotton, wood and wood products have also increased significantly (Table 23). Noticeable increases in imports of fruits and nuts had also occurred (mostly due to increase in cashewnut import which is mainly for reexport as processed cashew). Huge imports of vegetable oils and pulses have depressed domestic prices of these commodities and adversely impacted their domestic production and the producers. India should develop policy to regulate trade of such commodities to balance interests of both producers and consumers. Since farmers, who are both producers and consumers, comprise about 60 percent of our population, the exercise of balancing the import and export of strategic commodities must be undertaken keeping in mind overall income and savings and livelihood security of small farmers. On the other hand, the country must be able to take full advantage of the bright prospects of increasing exports of high value commodities such as fruits, vegetables, fish and livestock products.

2.11.A.55 Cost competitiveness and product quality issues are critical to compete in World market. Research and technology development should be geared and focused to increase the overall competitiveness of our major crops and commodities. This
calls for enhanced and sustained efficiency of inputs use, thus cutting cost of production, improving quality and reducing post-harvest losses so that the input-output ratio is maximized (without sacrificing the ecological and environmental security). International quality and safety standards for agriculture products are very high. Meeting of their standards involves substantial costs for building technical and physical capability. There is a need for pooling talents and resources available in both public and private sectors to build this capacity. Finally, public research system should shoulder the responsibility to protect small farmers from ill-effects of trade reform process.

2.11. A.56 Along the production-processing-marketing chain, commodity-specific detailed action plan should be prepared with clearly defined goals. India’s preparedness in the field of SPS measures is highly inadequate. As a result of which, several of our consignments get regularly rejected. The situation is likely to get still worse in the coming years as the Codex Alimentarius Safety Standards get more and more stringent, let alone the fast shifting of the goal posts. Thus, the urgency of the launching of quality and food literacy movement in the villages and strengthening of SPS infrastructure can hardly be overemphasized. A **Food Safety Council of India, chaired by the Union Minister of Agriculture, with the Union Commerce Minister as co-Chairman, should be established.**
2.11. A.57 We must urgently augment and create survey, surveillance and quality literacy programmes. The SPS infrastructure should be brought at par with International Standards and awareness should be generated abroad on steps taken by India to maintain high standards regarding food safety and biosafety. Keeping in mind high prospects of enhancing livestock export from India, the food safety concerns for livestock products will particularly be important since livestock economy is the backbone of a large number of marginal farmers and landless agricultural labourers. But today large parts of livestock product international trade are restricted because of animal diseases and threat of Avian Flu looms large. **ICAR’s work on animal diseases and risk management assumes extremely high priority for addressing these concerns.**

### 2.11. B.0 Policy and Paradigm Shifts

"**Ahead of us lie dangerous times. There are serious problems that derive from the realities of the external world, climate change, loss of biological diversity, new and re-emerging diseases, and more. Many of these threats are not immediate, yet their nonlinear character is such that we need to be acting today**”

(Lord May of Oxford, 30 November 2005)

2.11. B.1 Future of our agriculture would depend upon the ability of farm families to raise agricultural productivity in perpetuity in an environmentally sustainable manner and enhance our global agricultural competitiveness though rapid progress in the areas of quality improvement cost reduction, diversification of farming systems and value addition to primary products. **Science is basic to sustainable intensification, diversification, value addition and quality improvement.** It is only science based and knowledge intensive agriculture that can help our farming families numbering over 115 million (25% of the global farm population) to enhance productivity without associated ecological harm. The Commission offers suggestions on methods of achieving a proper match between scientific research and the knowledge and technological requirements essential for launching an “ever-green revolution” or sustainable agriculture movement. Even at the outset, it must be stressed that an annual growth rate of 4% in agriculture will need a 8%
growth rate in horticulture, animal husbandry and fisheries, thus emphasizing the need for a farming system rather than a commodity centered approach to research.

2.11.B.2 National and international policy actions should ensure that science and technology must specifically address the needs and prospects of majority small and resource-poor farmers and help mainstream the gender concerns. Institutional, human capital and policy supports must capture the positive effects and minimize the negative effects of globalization and liberalization and of revolutions in biotechnology and information and communication technologies. A meaningful interaction between science and policy and between scientists and policy makers is needed to promote knowledge economies and to bring the much-needed congruence among productivity, sustainability, profitability and equity. Thus, it is not only biological and physical sciences, but also economics and social sciences, which must all interact dynamically to yield wholesome results.

2.11.B.3 Urbanization and globalization have fuelled dietary convergence and dietary adaptation. These present both an opportunity to reach lucrative new markets and a substantial risk of increased marginalization of smallholders and poor people leading to even deeper poverty. Smallholders must organize themselves in cooperatives or as Small Farmers’ Estates to enhance their economies of scale and competitiveness and should be supported both by the public and private sectors for training and skill development and start-up funds.

2.11.B.4 The need to accelerate agricultural production can hardly be overemphasized. However, quick fixes and short term economic gains, particularly those with heavy social and ecological costs, must be avoided. For instance, the conversion of vast paddy fields into saline aquaculture in Southeast Asian countries which saw a short lived boom but busted soon, caused serious land degradation. National policy priorities for preventing land degradation and managing degraded lands must be determined and judiciously implemented.
2.11.B.5 There are pressures for diverting water from agriculture to other sectors. IFPRI has warned that re-allocation of water from agriculture can have a dramatic impact on global food markets. Policy reforms are needed from now to avoid negative developments in years to come. These reforms may include the establishment of secure water rights to users, the decentralization and privatization of water management functions to appropriate levels, the participatory and community involvement in regulatory and pricing reforms and markets in tradable property rights, and in the introduction of appropriate water-saving technologies. **Community land and water care movements** should be launched to ensure commitment of the masses towards conservation and judicious use of water and other natural resources.

2.11.B.6 Likewise, major policy and management changes are needed to realize full potential of fisheries consistent with cultural and social concerns of all stakeholder groups. The dark side to the new fish boom should be discouraged. As regards livestock, the high environmental cost of intensified industrial livestock production and the environment friendly widespread mixed farming systems of majority small and landless farmers should be judiciously balanced through appropriate policy and technological interventions. **“Lack of policy action will not stop the Livestock Revolution, but it will ensure that the form it takes is less favourable for growth, poverty alleviation, and sustainability in developing countries”**.

2.11.B.7 Conservation of forests is closely linked with the status of agriculture and livelihood security of people living in and around forests. Small and poor farmers account for 60 percent of rain forest destruction, converting forestland to agricultural land to meet their food needs and to earn a living. **“In fact, when a farm household in the humid tropical forest margins slashes and burns as the initial step in an agricultural cycle, it starts clock ticking”**. Integration of social status, physical infrastructure and agricultural productivity of forest margin areas with the overall national economy will greatly reduce the pressure on forests and forestlands.

2.11.B.8 Policy towards minimising the erosion of the treasure of biodiversity should be a high priority. The FAO-led International Treaty and Global Plans of Actions on Plant Genetic Resources for Food provide the mechanism for rationally conserving and
utilizing genetic resources. Dynamic national research systems should be in place to address the research, development and sharing issues of germplasm. Biotechnology should increasingly be used for characterization, conservation and utilization of genetic resources. On the pattern of UNESCO's Human Genome and Human Rights, FAO should adopt a universal declaration on the "Plant Genome and Farmers' Rights" to provide a balance between the rights of conservers of biodiversity and the researchers, developers, and users of modern biotechnological products. There is an urgent need to develop guidelines and procedures for the realization of Farmers' Rights to sustain on-farm in-situ community based conservation of biodiversity and associated traditional knowledge. A fair, gender sensitive, transparent and implementable reward and recognition system should be created for this purpose.

2.11.B.9 Science can greatly promote inclusive development by addressing the needs and opportunities of poor, less-favoured areas, neglected and excluded communities. Even biotechnology can be geared towards this cause. As repeatedly emphasized by Nobel Laureate Amartya Sen, the lack of entitlement to basic resources is the main cause of hunger and poverty. Scientifically informed agrarian reforms to grant titles to land and water, and increased access to credit, knowledge and markets, will enhance productivity, sustainability (through better land and water care) and income, thereby resulting in appreciable reductions in hunger and poverty. Engendering these changes and technologies and socioeconomic safety nets designed for small-scale and marginal farmers are essential for supporting rural livelihoods, and this aspect should be explicitly highlighted in national policies.

2.11.B.10 The existence of an enabling environment to judiciously exploit scientific and technological developments is as important, if not more, as the technology itself. Policy provisions must humanize technologies, and should emphasize: (i) enhancing capabilities for sustainable livelihood, and providing for new livelihood opportunities for the poor, (ii) improving the productivity, profitability and sustainability of communities' assets, and establishing effective linkages between community mobilization and the government and other service providers, (iii) ensuring the congruence and synergism among environmental, economic and social (gender and other equities) securities, and
empowering communities, especially the vulnerable ones, to harness new and
appropriate technologies and enabling them to blend traditional local technologies with
morden technologies.

2.11.B.11 Science and technology development must continue to spearhead the
productivity-enhancement process. Sustained intensification through increased yield
per unit land area, water, labour, and capital is the only recourse for achieving the
production targets. In retrospect, the Green Revolution had its own strengths and
weaknesses. The unprecedented production and yield increases and improvements in
food supply and rural economy notwithstanding, it had the following shortcomings:

- Maximization of yield potential of only three cereal crops (rice, wheat and maize),
  albeit most important from the view point of food security, and that too only
  under irrigated or assured rainfall conditions, thus bypassing the vast rainfed and
  non-congenial areas and a large number of other important crops.
- In the initial years, it was suited generally to resource-rich farmers who could
  afford inputs, hence resource-poor farmers with little input capacity could not buy
  into the revolution, atleast in the early stages, thus enhancing inequality.
- It largely ignored the environmental costs.

2.11. B.12 The above shortcomings must be avoided as we launch the Second Green
Revolution as recently emphasised by our Hon’ble Prime Minister, Dr. Manmohan
Singh. In this context, the researchers must ask themselves the following questions in
deciding their research and technology development priorities:

- Will the technology lead to higher productivity across all farms, water regimes
  (rainfed drylands), soil types and regions, not just well-endowed ones?
- How will the technology affect the seasonal and annual stability of production,
  especially the highly risk prone rainfed areas suffering from high instability?
- How will the technology affect the energy balance, eco-system and the
  sustainability of farming?
- Who will be the winners and losers from the technology – and how will it affect
  the majority small and marginal farmers, the poor and deprived ones?
2.11.B.13 Paradigm shifts will be needed to address the above and other related questions. The first paradigm shift relates to a shift in research approach from a single commodity based and monodisciplinary to a farming system based and multidisciplinary. The second shift demands a change from a top-down (training and visit system) extension approach to a participatory (effective research-extension-farmer-market interface) approach of technology assessment, refinement and transfer. The third shift seeks the integration of molecular biology, bio-technology and bio-information with conventional as well as traditional technologies (ecotechnology) for speedy, more precise and wholesome gains. The fourth shift seeks greater congruence between productivity sustainability and equity and creation of enabling mechanisms and inclusiveness for generation and adoption of new technologies. Cost-effectiveness of production, quality and safety in food and other products, and GMO biosafety and biosecurity, will assume high significance in the globalised and liberalized world. These paradigm shifts should be comprehensively internalized in national policies on agriculture and agricultural research and technology development.

Women in Science and Science for Women: Technological Empowerment of Women – Humanising Science and Technology

2.11. B.14 Countries with lower achievement in the Human Development Index and Gender Development Index have a larger percentage of their economically active population (both male and female) employed in the agriculture industry. Second, these same countries have a higher proportion of economically active women involved in agricultural activities relative to men. The disparities are likely to increase as rural to urban migration continues to change the composition of rural areas putting even greater responsibilities for the growth of the agricultural sector on women than they already have. In aggregate, women in rural areas in the poorer countries will be impacted most heavily as the feminization of agriculture intensifies further. Agricultural technologies specifically designed to improve the efficiency and productivity of the female labour force will thus greatly improve overall agricultural productivity.

2.11. B.15 There is lack of analytical understanding of the gender inequality. Social research must provide disaggregated information on rural woman that can feed into
policy formulation, and that can help articulate the strategic gender aspect of demographic transition. There is a lack of organized empirical evidence and of key information on the negative impact of the gender bias - as of unpaid work of rural women within the family, child labour, inadequate nutrition for mothers and children, inequitable access to credit and support services and to health and education facilities. This gap contributes to the continuing inability to influence those agricultural policies, programmes, and policy makers that affect rural women. Science must help gender mainstreaming to fully realize this huge human capital wherewith to combat hunger and poverty.

2.11. B.16 The National Commission on Farmers, in cooperation with the National Academy of Agricultural Sciences and the M.S. Swaminathan Research Foundation, organized a brainstorming session on the role of Women in Science and Science for Women, November 2005, to review the progress since the Fourth Women’s Conference held in Beijing in 1995. Recognizing the increasing feminization of agriculture and further realizing that agriculture in the years ahead will be essentially science-led and knowledge-based, the meeting appreciated that

(i) a people-centric sustainable development should ensure women’s equal access to economic resources, land, credit, science and technology, vocational training, information communication and markets,

(ii) S&T have to be developed, disseminated and harnessed in a gender sensitive manner with equal participation of women not only in S&T development but also by women who are the end users, and in strengthening the health, nutrition and livelihood security of women, and

(iii) there is a greater need for self sensitization, confidence building and psychological management.

In order to ensure the above, the Commission strongly recommends to strengthen the following areas:
2.11. B.17 **Women in Science**

- Promote the full participation of women in all S&T activities and ensure their full and equal participation, by taking into account the multiple burden on their time and creating suitable support systems to reduce this strain.

- Enhance the retention of girls in the leaky pipeline especially at the tertiary level and the mid-career women by bringing in flexibility in procedures and personnel policies to meet their special needs.

- Assess and draw up appropriate schemes to enhance their professional participation and increase the number of fellowships, opportunities for participation in conferences/workshops and increase their representation and participation in decision making and Professional Bodies as well as institute many recognitions and reward systems for their meritorious works.

- Prepare an electronic directory of women scientists and technical personnel as a reckoner for facilitating and enhancing their participation in scientific meetings and decision-making committees.

- Promote entrepreneurship among interested women by drawing up innovative schemes which help in the incubation and scaling up of innovative ideas which address the specific needs of women and establish special venture capital fund for enabling women entrepreneurs to take to a career of self-employment in converting new technologies into market-driven products.

**Science and Technology for Women**

*Skill Empowerment*

2.11. B.18 Skill empowerment of women is fundamental for harnessing science and technology for livelihood security. In this context, the following actions are needed:

- Identify appropriate technologies for multiple livelihoods, enhance incomes and improve the way of life of poor and vulnerable women.
• Draw up well coordinated programmes to reach the rural women through well networked models for technology transfer, demonstration, dissemination and adoption.

• Establish training and mentoring centres for the rural women at households, SHGs, Farm women and Farm labourers. Capacity building centres on the model of KVKs should be established soon.

• Establish rural technology parks which will also help in adoption of appropriate technologies, to address local problems like reduction in drudgery and occupational hazards, appropriate tools, identify income generating activities – provide a platform to assess the real needs and feed to S&T institutions as agenda for research.

• Identify and promote micro enterprises based on assured and remunerative markets, low transaction cost and economic viability, preferably in horticulture, including medicinal and aromatic plants; village level agro-processing and value addition centres, organic farming, etc.

• Increase easy access to credit and markets to enhance multiple sustainable livelihoods; develop micro-credit programmes into ‘Livelihood Finance’ systems which involve provision of credit together with appropriate services in the areas of technology, training and trade.

• Induce financial institutions to address issues like flexibility, sensitivity of the needs and status of the poor women so that they have an easy access to credit.

• Promote ICT based information service like e-governance, e-agriculture, e-education, e-medicine, e-commerce etc. through the Mission 2007 Every Village a Knowledge Centre which should have provision for appropriate contacts and follow up programmes to help those seeking special assistance.

**Generic Catalytic Interventions**

2.11. B.19 The following steps and activities will further enhance the cause of science-led improved livelihood security of women:
• Engender the curriculum at the school level and technical education (Medicine/Engineering/Agriculture) level for gender sensitivity among future scientists and development personnel and strengthen S&T education and communication skills among community development workers.

• Engender all technology mission mode programmes and conduct periodic gender audit, the experience will help in preparing guidelines for the inclusion of women in other technology-based or technology-rich programme areas, especially the National Horticulture Mission, Bharat Nirman Programme, Capacity Building & Monitoring Centres for SHGs and revitalization of KVKs.

• Generate disaggregated gendered data on the impact of S & T on the livelihoods of rural women.

• Harmonize all activities and schemes coming under different Ministries/Departments so that women benefit optimally, ensure adequate resource allocation for women under various programmes and implement equal wages for equal work.

• Establish a **Network of Women Scientists and Institutions** interested in engendering the development through S&T based interventions to develop an end to end approach for the various agro-climatic zones. Such a national level action and policy research network should carry out longitudinal studies of women’s roles in agriculture and rural livelihoods in the various agro-ecological regions of the country.

• Give greater focus to extension services in all areas of technology and build a strong cadre of extension workers, who may be given frequent exposure for sharing these ideas with the members in the group.

• S & T applications should foster job-led economic growth and not jobless growth. The opportunities for rural women to earn their daily livelihood through mini-enterprises and vending methods of marketing should be safeguarded by introducing engendered employment impact analysis.
**Filling Critical Gaps to Enable Unreached Women to Benefit from Science and Technology**

2.11. B.20 The critical gaps in taking the benefits of S&T to the unreached women should be filled in the areas of health, food and nutritional security, agriculture and entitlement. As regards health and nutrition, strategies should be enhanced to address anemia and hidden hunger caused by micronutrient deficiencies, particularly iron, iodine, zinc, vitamin A and B-complex vitamins and to promote conservation and revitalization of the traditional landraces and ethnic foods inclusive of wild edible foods to diversify the food basket. In Agriculture, the role of women should be promoted in the conservation-cultivation-consumption-commerce chain. Women’s access to production, input and credit resources), and to Common Property Resources should be enhanced. Appropriate technologies and support services should be provided to enhance their use in a participatory and productive manner. Their capacity should be enhanced in water use/management and augmentation and in harnessing renewable energy like biomass, biogas, solar and wind. The various Acts, especially the BD, PVP&FR should be engendered and a literacy drive should be launched to understand them.

**Participatory Research and Knowledge Management**

2.11. B.21 Often the situation under which the scientific information is generated is unlikely to be same from those operated by the farmers. The scientific information is to be reviewed in terms of specific needs, opportunities and constraints faced by farmers in different production systems. The typical contrasts in physical conditions under which the farmers operate in terms of topography, soils, plot size, hazards, the facilities of irrigation, size of management unit, farming systems, nature of production stability, production sustainability, and priority for production need to be considered. The Small Farm Production Systems have some typical characteristics which include strong interaction between land and household economy, interlink of on and off farm activity, highly diverse, complex and risk prone activities even within systems, predominance of household inputs, prevalence of traditional practices, multiple enterprises primarily for domestic needs, production systems highly susceptible to stress and perturbations, and dependence on family labour and further sharing. The assessment and refinement of
technology thus need to be site specific, holistic, farmer participatory, and technical solutions to existing problems should be inter-disciplinary, interactive, iterative and gender sensitive.

2.11.B.22 Essentially the assessment and refinement of technology needs discipline to programme mode, piecemeal to system approach, open ended to focused technological intervention, “take it or leave” to demand-led approach, integration of biophysical and socio-economic factors, institute to inter-institute mode of technology assessment and refinement, and overall a strong research-extension to research-extension-farmer-market linkage and overall proper appreciation of distinction between science and technology. Different types of farmers’ participation are used for conducting on-farm trials for different purposes. In a truly participatory and collaborative, even collegiatic manner, the farmers must actively participate in on-farm trial process and be involved in regular meetings designed to clarify the logic, their current practices and their demand for new technology. The farmers must participate directly in the planning and execution of trials and analysis of the results and the knowledge should flow both ways.

2.11.B.23 A farming system is unique and reasonably stable through dynamic arrangement of farm enterprises that a household manages in response to the physical, biological and socio-economic environments in accordance with the household’s goals, preferences and resources. These factors combine to influence both the output and production methods. The farming system is a part of a larger system and can be divided into subsystems. On the regional level there are the non-agricultural systems, the market and credit systems as well as the farm systems. Within the farm subsystems there are the crop, animal, soil, weed, insect and other subsystems. Thus, the farmer must occupy the centre stage in refining, adopting and adapting the technologies. The approach should involve selecting target areas and farmers, identifying problems and opportunities, designing and executing on-farm research, and evaluating and implementing the results.

2.11.B.24 While identifying the solutions from on-farm trial, it must be seen that the technology will function and its profitability, compatibility with the farming system, contribution to reducing risk, need for institutional support and ease of testing by farmers
The assessment of trials should be based on net income to the farmer assessed through economic analysis and ability to solve the problem diagnosed through. The results of promising pilot activities should be extrapolated for defined groups of farmers in specific defined areas (clientele). The Farm School approach should be adopted for grassroot level training and technology diffusion, for which the R&D system must provide the needed financial and technical support.

2.11.B.25 In a real community situation, seeking participation and ensuring the same on a regular basis is essential to develop useful technologies. To ensure genuine participation is a crucial art. There is a need for attitude change on parts of the stakeholders, particularly the researchers and extensionists. The public sector researchers need to be proactive in participation especially in more difficult conditions. The following steps will prove helpful:

- The institutions in which they work have to be committed to produce results of use to an identified set of clients.
- Performance criteria, the means of assessing work against these criteria and the types of reward and incentives provided must all be geared to success in delivering technologies to meet clients’ needs.
- Scientists will need specific training in participatory methods. Providing that due recognition is given to their potential shortcomings, training in PRA methods is a good first step. But the scientists must be given the resources for field work to pursue some of the research issues identified by PRA, and should go beyond mere diagnosis.

2.11.B.26 In the whole process of participatory research and technology development, researcher is most crucial person to ensure success. The local perception of research some times does not match with the participatory approaches. People also lack capacity to work together as there was no tradition of participation in India for a long time. This problem is still more pronounced when it comes to researcher and extensionists working together. This is an unfortunate legacy of the top-down research and extension. In the participatory mode, both the researchers and the extensionists need to develop positive
attitudes and empathy not only towards each other but also towards farmers. Since location specific research based on farmers’ needs will be more relevant to the farmers, the research stations of the SAUs and the KVKs need to be strengthened with better quality staff who are dedicated, trained in need identification and are able to formulate projects accordingly and should have freedom to initiate their own research studies based on local problems. MANAGE and NAARM should emphasise this approach in their training programmes. The ongoing programmes on researcher-extensionist-farmer linkage, such as National Demonstrations, KVKs, ATMAs, Lab-to-Land and Land-to-Lab Programme and Integrated Watershed Programme (to enhance productivity of every drop of water) and others should be sensitised to this requirement and their staff at all levels should be trained in adopting the participatory approach. Some of these programmes, such as Lab-to-Land, need to be revitalized and strengthened. The SAU’s Extension Departments should be reference centres, giving latest and credible information and advice.

2.11.B.27 Participatory (Farmer) breeding and knowledge sharing for development and diffusion of farmer-selected and scientist-assisted varieties combining proven adaptability to local agro-ecological, social and cultural milieu as well as possessing speciality traits (aroma, medicinal value and tolerance to local biotic and abiotic stresses) has emerged as an important strategy for harnessing treasures of our time-tested and ever-evolving indigenous knowledge and genetic resources. Several national and international programmes viz. the CGIAR Centres and the Indo-UK (DFID) programme have been promoting this approach. Some of these have been remarkably successful. For instance, the farmer participatory rice improvement programmes of the M.S. Swaminathan Research Foundation on Kalajeera (a high quality aromatic rice) in Orissa and Navara (a medicinal rice in Kerala) have tremendous potential of enhancing income and livelihood security of farmers in those areas. Such initiatives should be strengthened through additional research and technology dissemination efforts by mentoring and supporting dedicated SHGs and by linking the producers with markets and by creating and capturing niche markets.
2.11.B.28 Participatory Research, Demonstration and Training (RDT) Centres (see 2.11.D.11) should be farmer-centric and should concentrate on demonstrating how to increase the output and income of farmers with small holdings and artisanal fishermen. Precision farming, hi-tech horticulture, monsoon management and mixed farming will be important components of the training programmes. The proposed National Board for Strategic Research in Agriculture (see 2.11.D.10) can work out the modalities of establishing such Centres at locations where the work done will have a large extrapolation domain. Priority may be given to dry farming, where the work done at CRIDA and ICRISAT has shown that amelioration of micro-nutrient deficiencies in the soil can help to improve yield substantially. Also, we can initiate a revolution in pulses production by covering 100,000 ha under hybrid pigeon-pea (arhar) during 2005-06. The concerned State Governments could be requested to provide about 100 ha of land free of cost for establishing such RDT Centres. The Centres should be autonomous, and managed jointly by farm/ fisher families and scientists. Panchayati Raj Institutions should be associated with the design and management of RDT Centres. These Centres should be designed to serve as windows into the new world of agrarian prosperity that awaits rural India. They should have strong linkages with the relevant SAUs.

2.11.B.29 ICRISAT in partnership with CRIDA, National Remote Sensing Agency (NRSA), SAUs, Central and State Government Departments, NGOs and Farmers Associations/Organizations have developed and tested an innovative integrated watershed development model for enhancing the productivity of rainfed agriculture, minimizing land degradation and improving the livelihoods. The pilot model was developed and evaluated in Adarsha Watershed at Kothapally in Shankarpally Mandal in Ranga Reddy district of Andhra Pradesh. The main components of the participatory consortium approach for community watersheds are:

- Farmers collectively identify and prioritize the problems for possible technical interventions, participatory planning and implementation of watershed development involving all the stakeholders.
A consortium of research and development organizations including NGOs provides technical backstopping to community watershed programmes.

Increased individuals participation is ensured by providing tangible economic benefits through *in-situ* water conservation of rainwater which is translated into increased productivity and incomes through integrated genetic and natural resources management (IGNRM) approach. Holistic systems approach for watershed management for livelihood improvement was adopted in place of compartmental approach adopted earlier.

Knowledge flow is facilitated by linking successful on-station watersheds and on-farm watersheds for strategic research.

Islanding approach is used in which a strategic research watershed is established within the macro-watershed/district to serve as a site of learning.

Cost effective and environment-friendly soil, water, nutrient, crop and pest management practices are promoted for wider adoption to raise the carrying capacity of the system.

Empowerment of communities, individuals and the strengthening of the village institutions is achieved for sustainable development.

Continuous monitoring and participatory evaluation by researchers and elimination of contractors for implementing the works has increased transparencies, overall performance and sustainability of the programme.

2.11.B.30 This holistic innovative model has changed the paradigms for watershed management in India where watersheds are used as an entry point for improving the livelihoods and protecting the environment. Main success of the model depends on implementation of participatory approach by the community, empowerment of the stakeholders, building the available institutions and community-based organizations and most importantly technical backstopping by the consortium. **The pilot model, covering 200 villages, has been highly successful in enhancing productivity, profitability and sustainability. The Consortium should be encouraged to replicate and upscale the model.**
2.11.B.31 During the past 20 years, many extension systems like the Training and Visit system (T&V) of the World Bank have been tried and later pronounced as failure. Recently, another World Bank loan supported system, termed “Agricultural Technology Management Association” (ATMA) was introduced. ATMA takes into account the deficiencies of the T&V system and adopts a farming systems approach to extension. If implemented in a manner that regards farm families as partners and innovators and not just beneficiaries, ATMA will represent an improvement over the earlier approaches to extension. The mindset of extension personnel should change from patronage to genuine partnership (Lab to Land and Land to Lab).

2.11.B.32 Ecologically-sound agriculture is knowledge intensive. An area rather than a single farm approach is needed to spread eco-technologies like Integrated Pest Management, Integrated Nutrient Supply and Integrated Natural Resources (Soil, Water) Management. Panchayati Raj Institutions should be involved in the social engineering aspects of group endeavour in eco-agriculture as stipulated in the Constitution 73rd Amendment Act.

2.11.B.33 As earlier recommended by the Commission, the KVKs, should be developed into Krishi and Udyog Vigyan Kendras in order to give concurrent attention to on-farm and off-farm livelihoods. Establishment of 50,000 Farm Schools in the fields of farmer-achievers were suggested in order to spread their impact through farmer to farmer learning. The economic credibility and viability of the technologies adopted by outstanding farmers will be a major advantage in the lateral transfer of technical know-how. Thus, Farm Schools can serve as the grassroot learning centres and they can lead to a learning revolution in farming, particularly in areas such as horticulture, green house cultivation, efficient systems of water conservation and use, organic farming, cultivation of GM Crops, cultivation of tissue culture propagated banana, spices and other crops, medicinal plants, plantation crops, dairy and goat farming, crop-livestock–fish integrated production system, aquaculture etc.

2.11.B.34 The SAUs/ICAR Institute–KVK-Farm School system of technological and skill upgradation of farming needs continuous feed back and advice from farm men and
women. In order to provide a structured opportunity for sustained scientist–farmer dialogue, it is suggested that a National Council of Innovative Farmers (see 2.11.D.18) may be set up for providing on continuing basis guidance on the technology and public policy requirements for achieving productivity, quality and value-addition revolutions in the 115 million operational holdings in our country. This Council may be serviced by ICAR, with DDG (Extension) serving as the Convenor. Members of the Council of Innovative Farmers may be appointed by the President of ICAR in consultation with the National Commission on Farmers. A National S&T Alliance (Consortium) for Rural Livelihood Security, as suggested by the Commission, may be established to synergise inputs of various concerned Departments and Ministries at grassroot level.

**Fostering Strategic Partnerships towards an Innovative System**

2.11. B.35 The modern concept of an innovative system emphasizes a pluralistic system of research providers that recognizes the comparative advantages of different providers, and complementarity that can be achieved by forging close linkages between different actors. The leadership of ICAR has noted these requirements and has taken a number of initiatives to promote such linkages. However, effective implementation needs greater awareness down the line. In particular, the growing role of private research and the implications for public institutions are not widely appreciated. Where the private sector can efficiently provide near-market research services with scope for appropriation of benefits, the public sector should be prepared to withdraw and play a complementary role. Private research is stimulated by strategic research support from the public sector, and there are many areas where public-private linkages can enhance the effectiveness of both sectors. Enabling institutional mechanisms, especially IPR protection and capacity within the public sector to manage partnerships, can help develop and sustain these linkages.

2.11. B.36 The externally aided projects like NARP, AHRDP, NATP and proposed National Agricultural Innovation Project (NAIP) reflect government’s response to the changing needs in the national agriculture research system. There have been major paradigm shifts in the approach as well as in activities in these projects to address
concerns of system efficiency through O&M reforms, research infrastructure capacity building, human resource development, and programme efficiency through production system, mission mode, team of excellence and competitive and project-based modes of research funding involving different stakeholders including private sector. Policy, incentives and regulations should be aligned to foster innovations and entrepreneurship in agricultural science. In order to attract brilliant young scientists to agriculture, a Genius Award for young scientists should be established. The emphasis to address emerging market context through research on value chain in a consortium mode involving all the stakeholders is yet another move towards management of change. The concern on declining emphasis on basic and strategic research must be addressed through creation of national fund for basic and strategic research by ICAR as a separate plan programme. A significant component of the proposed NAIP should also strengthen basic and strategic research.

2.11. B.37 The proposed India – US knowledge initiative on agricultural research and education is a realization of the tremendous scope to complement the capabilities of the two countries being leaders in different fields of science and technology. The initiative is an effort towards addressing problems such as global warming, new pest-disease complexes, resource depletion and degradation, household nutritional security, slow growing farm profitability, and increased competition. Sharing of recent developments in cutting edge technologies, such as nanotechnology, should be high on the agenda. It is recommended that the NAIP should internalize these initiatives alongwith the proposed strengthening of scientific talent, technology acquisition and public-private partnership.

2.11. B.38 The IPR and other enabling regulatory measures should be harmonized nationally and internationally to reward the incentives as well as to protect the poor. The International Agricultural Research Centres (IARCs) of the CGIAR have long been interacting with the private sector, and mutually benefiting thereby. Some of the centres have formalized their collaborations through agreements. So far, the CGIAR system has been able to share its technologies and products as international public goods. The CGIAR policy must carve out a system which will allow a continuation of the free
flow of technologies to the poor, without jeopardizing their partnership with the private sector. Financial and other supports should be extended to the CGIAR system to enable it to pursue frontline research to generate highly competitive technologies and to leverage benefits from the spillover effects. Linkages should be established among IARCs to build complementary Centres of excellence and avoid duplication of efforts.

2.11. B.39 Private sector R&D institutions are growing in India, particularly in the areas of biotechnology and crop breeding. It is high time that we develop Codes of Conduct for public-private sector partnerships based on respect for each other’s obligations. Not-for profit R&D institutions also exist in the NGO sector which can also adopt the same Codes of Conduct as public-funded institutions in their partnerships with the private sector, where IPR, Breeders’ Rights and other forms of proprietary control over technologies and products of commercial significance are important. The Codes of Conduct should be developed through extensive consultation among all partners so that these could be used in the entire national scientific research system. The Commission recommends the following additional measures to further strengthen the partnership:

- Provide tax incentives, including tax holidays, so as to increase private sector’s contribution to R & D from 14% to 33%;
- Strengthen national capacities in regulatory matters, especially IPR, SPS and quarantine facilities to promote technology acquisition as well as trade;
- Encourage testing of new varieties bred by private sector and their other technological products in the public sector supported national technology testing programmes; and
- Undertake joint research activities with clearly defined responsibility, accountability and profit sharing.

2.11. B.40 Public private partnership in high value agriculture is a necessity and involvement of smallholders is crucial for achieving inclusive and equitable development. The role of the corporate system in the overall food chain is becoming important, highlighting the need for greater and effective linkages between public and private sectors in the changing food situation of the country. This linkage must be
addressed by the country’s innovation and research system. Indian supermarkets are increasingly retailing and distributing not only processed food but also fresh vegetables and fruits and other agricultural products and are playing an important role in the food chain. This has also put an increased pressure on food management and processing. In this transformed scenario, we must not forget the role of small and marginal farmers who are not only producers but also constitute the bulk of the poor consumers as customers. Small farmers thus must get a foothold in this changing food chain, but the major problem is their smallness causing higher unit transaction cost to participate in the system.

2.11.B.41 The rising consumer income, especially in the non-agricultural sector and urban areas and changing life-style, are creating bigger markets for high value agricultural products like fruits, vegetables, fish, eggs, milk and meat. The growing markets for these products present an opportunity for farmers to diversify their production out of foodgrains and raise their incomes. Annual growth rates of the order of about 4 to 6 percent in these commodities vis-a-vis 1 to 1.5 percent in case of cereals were registered during the last ten years and the trend is likely to continue in the years ahead. The enhanced production of the high-value products will push up processing and marketing of these products creating a lot of employment in rural areas.

2.11.B.42 In order to mainstream the small landholders into the high-value agricultural and supply chain, the strategic partnership between public and private sectors will be needed. Such an arrangement should be built to pool risk and resources to bring actors together to resolve market failures witnessed in developing countries. Supply chain plays important role in cooperation of the partners to specify high quality products to generate value and consumer demand. Such a win-win situation is particularly favourable for smallholders in terms of higher prices, knowledge, reduced losses and assured markets. However, smallholders are not able to make these demands due to market failures attributed to information asymmetries, organisational failure, high transaction cost and regulatory failures. The synergy of the public-private partnerships, especially involving the smallholder is bound to create mutual benefits and confidence
and can remedy market failures which cannot be undertaken separately by public and private sectors. If kept out of the chain, implications for smallholders are depicted in Figure 15.

**Figure 15. Implications of Exclusion of Small Holders from Market Chain on their Economic Activities**

2.11. B.43 The market failures can be remedied through: creation of research contribution to deliver high quality varieties, particularly suitable for processing, development of third party certification organization and public-private-partnership-led (PPP-led) initiative to create producers’ organisation to improve marketing and build linkages with processors, as suggested in earlier reports of the NCF in relation to the creation of Small Farmers Estates (SFEs) on the NDDB
model. The PPPs must be at the chain-level to intervene in all major bottlenecks, as targeting one may not benefit the whole supply chain. Bulk vending should be promoted to cut cost and also to mainstream small producers in market chain. Establishment of effectively functioning rural warehouses and transport connectivity and facilities, especially in hills and mountains and dryland arid zones, will be essential for linking the smallholder with the market chain. The PPPs must also induce positive effects for all stakeholders, processors, retailers, etc. to ensure a positive feedback and benefit to the whole supply chain. For keeping the system dynamically responsive to new situations with optimum output for all the partners, it may be prudent to ponder as to how to identify appropriate partners and modalities to scale-up PPPs and as to how can PPPs regulate market failures.

2.11. C.0 Funding of NARS and Strategic Financial Strengthening

2.11. C.1 The complexity of development challenges, the urgency of meeting the challenges and the unprecedented technological revolution (including ICT revolution) provide uncommon opportunities to the national agricultural science, research, education and technological development system to appropriately and synergistically strengthen and position itself to meet national goals as well as international commitments, particularly the Millennium Development Goals - especially halving the number of hungry and poor people by 2015.

2.11. C.2 As discussed earlier, investments in agricultural research, science and technology development are not only low (as compared to several developing and most developed countries) but also have been stagnating in the recent years. Some of the new emerging challenges and opportunities, such as climate change, nanotechnology, value addition to biomass, integrated and precision farming systems, participatory breeding and scientific organic farming, have barely been addressed. Knowing that the rate of return on investment in research in India has been high and the country is faced with complexer problems seeking technological solutions, the need for increasing investment in agricultural research can hardly be overemphasized. Not only the level of funds but also the efficacy of allotment of resources and the various mechanisms for
maximising the return on investment in agricultural research in terms of economic gains, social equity, environmental sustainability and ecological security need to be improved.

2.11. C.3 Our Prime Minister has repeatedly emphasized that agricultural revival and farmers’ well-being are the top priorities of the Government. The Common Minimum Programme of the UPA Government states, “The UPA Government will give the highest investment, credit and technological priority to the continued growth of agriculture, horticulture, aquaculture, floriculture, afforestation, dairying and agro-processing that will significantly add to the creation of new jobs. … will ensure that public investment in agricultural research and extension, rural infrastructure and irrigation is stepped up in a significant manner at the very earliest. … will ensure that adequate protection is provided to all farmers from imports, particularly when international prices fall sharply. … will follow policies and introduce programmes that strengthen India’s vast science and technology infrastructure.”

2.11. C.4 To a certain extent, the above declarations are being backed up by fund allocations and other supports in varying measures. One of the major recent initiatives is the Bharat Nirman - a time-bound business plan for action in rural infrastructure for the next four years. “Under Bharat Nirman, action is proposed in the areas of irrigation, road, rural housing, rural water supply, rural electrification and rural telecommunication connectivity. We have set specific targets to be achieved under each of these goals so that there is accountability in the progress of this initiative (Prime Minister).

2.11. C.5 The Finance Minister in his Budget 2005-06 statement had observed “Agricultural Research has a vital role to play in the strategy for reviving and encouraging diversification. Our agricultural universities and research institutions have done good work in the past and now need to be strengthened and modernized. A Task Force headed by Dr. M.S. Swaminathan has recommended the creation of a National Fund for Strategic Agricultural Research. I am happy to announce an initial provision of Rs 50 Crore for operationalising this Fund.”

114
2.11. C.6 It is most heartening that the Central Government has decided to establish a National Science Education and Research Foundation for frontline research in science and has approved Rs 1000 Crore for commencing two institutions, one in Kolkata and one in Pune. The National Commission on Farmers applauds this move and wishes to emphasise that similar strengthening of selected flagship agricultural research institutions and strategic research and technology development programmes is essential to meet the formidable challenges and to capture the uncommon opportunities in agriculture.

2.11. C.7 In line with the above, the Commission recommends a provision of Rs. 1,000 Crore as a one–time grant to NARS to bridge the critical gaps in scientific infrastructure in frontier areas of technology, so as to enable the Nation to enhance its agricultural competitiveness and to benefit from science-led agricultural transformation.

2.11. C.8 The suggested additional allocation will particularly strengthen the following areas: conservation of livestock heritage of the Nation by establishing field gene banks and undertaking systematic genetic improvement of local animal breeds, especially in rainfed drylands and geared to the needs of small and resource-poor farmers; strengthening of genomics, bioinformatics and other cutting edge biotechnologies; harnessing the gene power of microorganisms, including bioremediation; enhancing use efficiency of plant nutrients and water; and value addition, low-cost processing and biomass utilization.

2.11. C.9 The additional investments in infrastructure and human resource development and technology incubation and dissemination will mobilize science also for ensuring the success of Bharat Nirman, National Rural Employment Guarantee Bill, Tribal Land Rights Bill and other such initiatives of the Government. This will auger well also with the Prime Minister’s call to the scientists to bring about a Second Green Revolution which would have special focus on dryland agriculture and would address the needs of small and marginal farmers (PM’s Inaugural Speech, 93rd Session, Indian Science Congress, 2006).
2.11. C.10 Several recent committees and reviews have suggested revitalization of the NARS on the above lines. For instance, the Swaminathan Task Group as well as Mashelkar Committee have identified IARI, IVRI and other premier national institutes to be designated as Institutions of National Importance (see 2.11.D.10 and 2.11.D.22). The Commission recommends that such institutes should be given special funds and organizational and management supports to empower them to enrich the Indian agricultural knowledge system necessary for enhancing country’s competitiveness at the global level on one hand and to serve the majority small and marginal farmers, often inhabiting vast rainfed drylands and other poorly endowed non-congenial agro-climatic regions, on the other hand.

2.11. C.11 As mentioned earlier, India has one of the largest NARS, covering the entire spectrum of crop, livestock, fishery, forestry, natural resources and agro processing and agri-business, but there are gaps in several areas awaiting redressal or are not receiving focussed attention. Some of such areas, as listed below, require more intensive and inter-disciplinary attention.

- Climate change and its implications;
- Harnessing space technologies, ICT, nanotechnology and other frontier technologies for precision farming;
- Organic recycling and value addition to biomass, biofuels and bioenergy production;
- Crop livestock-fish integrated production systems;
- Pre-breeding and participatory breeding; and
- Scientific organic farming.

2.11. C.12 The Commission recommends setting up of new National Centres/Institutes in the above areas or mandate existing ones to address those areas specifically. Such institutions could be set up in existing ICAR institutes or SAUs but should be functionally and financially autonomous with their own Governing Boards. The National Institute for Space Applications and Precision Farming could be set up jointly by ISRO and ICAR in the land available to ISRO at Hyderabad. The National
Institute for WTO concerns in Agriculture could be set up jointly by ICAR, the Ministry of Commerce, APEDA and MPEDA. It should have wings for capacity building in IPR and SPS (sanitary and phytosanitary measures). The National Institute for Biofuels could be set up by ICAR and MNES. In Commission’s view, the institutions should be built around outstanding scientists and research leaders of proven capability in these fields. Such committed research leaders should be first identified and involved in the project design process.

2.11. C.13 Further, the 10th Plan Steering Committee for Agriculture, Chaired by Prof. M.S. Swaminathan, had identified National Challenge Programmes and priority areas to be led by Scientist-achievers in a time-bound manner, intended to harness the power of partnership among appropriate institutions and scientists. These will address issues related to climate change, WTO concerns, gender dimensions, productivity, profitability and sustainability of organic farming, dryland farming, pulses and oilseeds production systems, bio-fuels, energy plantations and biomass-based power generation, coastal farming systems, including sea water farming, medicinal plants and herbal biovalleys, abiotic stresses with particular reference to drought and salinity, new animal and fish feeds and new vaccines for establishing disease-free zones in livestock production. Adequate resources should be allocated to these challenge areas.

2.11. C.14 In addition, the need for additional support for prototype manufacture of new implements and their wide-spread testing, quality assurance and effective popularization, particularly for enhancing productivity and profitability of farmers, can hardly be overemphasized.

2.11. C.15 The Commission recommends that the ICAR should position itself to effectively utilise the available and the funds requested above. Unfortunately, some of the allocations are not being systematically and effectively used by the concerned organizations. For instance, the provisions under the National Fund for Strategic Agricultural Research (NFSAR) are yet to be operationalised. A National Board for Strategic Research in Agriculture (NBSRA) may be set up to coordinate and harness advances in Basic Sciences for agricultural progress. A couple of well-chosen
strategic research and technology development programmes (with high potential socio-economic and agro-ecological pay-off) should be launched by the ICAR without any further delay. Based on the preliminary outcomes, additional funds should be requested under the NFSAR. Obviously, prompt decision-making, project/programme formulation and effective governance are called for utilizing the resources for strengthening our research, especially strategic research.

2.11. C.16  **Besides intensity, sustainability of the funding is also important.** The current funding situation is not sustainable for a number of reasons. First, increased funding has not matched the continuing expansion of the number of R&E institutions, resulting in a steady increase in the share of salary and overhead expenditures at the expense of operating expenditures. In ICAR, the salary to operational expenses ratio has increased to 70:30 against a target of 60:40 and the situation is even more serious in the SAUs. New resource generation opportunities such as payments for services by farmers, growing high value crops (commercial livestock and fruit crops), income generation through commercialization of technology and services, and contract research with the private sector are emerging and should be tapped. This will require development of capacities in IPRs and business skills in public research organizations. However, resource generation will not fill the gap. **Public funding should be increased to 1% of AgGDP and priority should be given to Central and Eastern States.**

2.11. C.17  The share of competitive funding is still low and uncertain. Because competitive funding has the potential to enhance accountability, quality and efficiency of the system despite somewhat higher costs in terms of overheads and time of scientists, a **higher share of funds should be gradually shifted to competitive funding.** Of course, regular block grants must continue in order to maintain and upgrade research infrastructure and to strengthen basic and strategic research.

2.11. C.18  **The roles of Centre and States in supporting R&D should be balanced and harmonised.** The distinction between the roles of the Centre and the States in agricultural research has become blurred over time. In practice, SAUs should have primary responsibility for applied and adaptive research to meet local demands in their
respective States, and ICAR should take the lead in strategic research that is relevant to several States, and in those applied research areas where States will tend to under-invest due to spillovers. However, SAUs are generally starved of operating funds and now largely depend on ICAR. A shortage of funding in the SAUs has had adverse effects on human resources development, research infrastructure, and linkages with farmers. There is an urgent need to sensitize policy makers at the State level to the payoffs to investing in research. At the same time, the Central Government might develop a funding formula that supports the weaker States, but provides incentives to stronger States to increase their funding (e.g., matching grants). A key role of Central research is to generate spillovers to enhance efficiency in State research programmes. In some areas, especially crop breeding, spillovers are pervasive. The AICRPs provide a mechanism for facilitating such spillovers.

2.11. D. 0 Institutional Reforms and Revitalising the NARS

Addressing Multiple Research Objectives

2.11. D.1 The Indian NARS must find a balance among multiple objectives, ranging from traditional food security objectives, to emerging demands to serve a more market oriented economy, to meet the needs of more sophisticated consumers, and to preserve the environment. Striking a balance between these objectives has major implications for organization of research, prioritization of the research agenda, and management of intellectual property. Since there are increasing demands on the public sector to provide technologies with characteristics of ‘public good’ and that address market failures in addressing social and environmental concerns, public research investment in India needs to close the gap with the global average of one percent of agricultural GDP as mentioned earlier. Also, public research institutions must work closely with key stakeholders to define priorities that address multiple objectives, employing formal research prioritization approaches. This is extremely important when the system is large in size, objectives are conflicting and clients are poor in articulating their research needs.
Intellectual Property Rights and Public Research

2.11. D.2  **IPR regimes should be part of agricultural development pathways and consistent with our own priorities and capacities.** IPRs are important because they offer possible mechanisms for stimulating research, enabling access to technology, and promoting enterprise growth, all for the good of society. As such, they are merely one tool in a range of policies that may be applied in specific contexts to further agricultural development (e.g. for supporting public agricultural research, regulating seed production and marketing, providing an enabling environment for agribusiness development, and empowering smallholders). Because the incentives provided by any IPR regime usually interact with various other factors it is difficult to identify unambiguous conclusions regarding the possible contributions and concerns that IPR regimes might present for Indian Seed Industry. There are several priorities for monitoring. These include assessing the extent to which IPR regimes (and other policy changes) affect the structure and concentration of the domestic seed industry, and determine the options available to smallholders. This also includes analyzing if farmers have equitable access to an increasing diversity of crop varieties and if the structure of the commercial seed market provides confidence for participants while at the same time encouraging new entrants.

2.11. D.3  IPR regimes in plant breeding should provide incentives for diversifying and strengthening plant breeding and seed production. This implies that policymakers cannot consider IPR regimes in isolation from wider issues of national agricultural policy. The role of the public research system may be a subject of considerable debate in light of generally declining national budgets and the growth of the private sector. The system needs to distinguish between using IPRs in order to facilitate the use and delivery of their varieties, and seeing IPRs as a contributor to institute budgets through royalty income. This requires knowledge about the costs of obtaining and enforcing IPRs, and a realistic assessment of the public system’s capacity to compete with the private sector in producing commercially viable products (or in rewarding and maintaining staff for this task).

2.11.D.4  The strategies that the public system adopt for using IPRs will depend on answers to fundamental questions about the role of public sector agricultural research.
For instance, different approaches to relations with the private sector must be taken into account. In addition, the way that public system manages IPRs has a significant bearing on the extent to which germplasm resources are shared more widely. There are still serious challenges with respect to delivering useful varieties, particularly of non-hybrids and so-called ‘orphan crops’, to smallholders. The combination of limited and isolated markets with widespread seed saving means that even fairly strong IPR regimes are unlikely to elicit commercial interest in the near future. **We must find ways of combining (largely) public plant breeding, appropriate formal seed delivery (most likely private or cooperative), and support to local seed diffusion mechanisms, to serve the farmers dependent on these crops.** Public policies need to ensure that farmers are conversant with, and participate in debates regarding possible IPR regimes; that they are well-informed consumers who understand their rights in agricultural input markets; and that their interests and priorities are reflected in the work of public agricultural research.

**Efficiency of Public Research**

2.11. D.5 The public sector in general in India suffers from centralization and bureaucratization that imposes high transaction costs at all levels. Despite having a certain level of autonomy, the research system is no exception. Although ICAR recognizes these problems and has initiated a number of organizational and management (O&M) reforms, there are still important gaps as well as problems in their implementation. **First, institutional rigidities imposed by commodity and disciplinary boundaries restrict the flow of information between hierarchies and organizations in a large system such as India’s.** The decision to review the functioning of the AICRPs—originally established to forge interdisciplinary and inter-institutional research—was an important step toward addressing these rigidities. But much remains to be done to decentralize and devolve power before transaction costs can be reduced to acceptable levels for efficient research management.

2.11. D.6 Second, there is a growing problem in the quality of scientific human resources owing to inbreeding in the system, especially in the SAU system, and
weakening of global scientific linkages. In the 1960s and 1970s, a significant proportion of scientists were educated abroad and Indian scientists were generally well integrated with regional and international networks. This situation has deteriorated significantly with scientists often working in the same institution in which they receive their PhD, and with professional isolation of many scientists. This trend must be arrested through assessment of human resource needs and use of foreign grants and loans for human resources development, and to support participation in international scientific networks and other initiatives. Advances in information and communication technologies also have much potential to foster such linkages and improve access to international literature and scientific data bases.

2.11. D.7 Third, research institutions require much improved accountability through institutionalization of objective and transparent evaluation mechanisms for planning, monitoring and impact assessment of research. Proliferation of research programmes has meant that many programmes serving small States and agro-ecological zones are inefficient. Much of the inefficiency is due to research programmes serving small ecologically- and politically-defined markets, so that even if they are productive in terms of technologies produced, they are only used in a small area. Resource allocation needs to be linked to research planning based on ‘bottom up’ approaches involving relevant stakeholders and feedback from monitoring and impact assessment. Implementation of such processes has been attempted several times, albeit with varying degrees of success. A prerequisite for its effectiveness is to link planning, monitoring and evaluation with funding decision and with performance evaluation at various levels—the system, institute, project and scientist.

2.11.D.8 Finally, although successive review panels of ICAR have raised these various concerns and proposed recommended changes, past attempts at reform have failed due to the lack of financial flexibility and autonomy of ICAR. A package of reforms aimed at enhancing autonomy, improving decentralization and devolution of power, and improved financial management through project-based budgeting is required. Both ICAR and SAUs should commit themselves to such reforms. Support of high level
policy makers at both the Central government and State government levels is needed to implement this far reaching reform agenda.

Revamping and Refocusing the NARS

2.11. D.9 The centrality of adequate financial resources for science-led growth notwithstanding, the allocation, deployment, outlay-outcome accountability as measured by accepted indicators is equally important, if not more. A Task Group, chaired by Prof. M. S. Swaminathan, Chairman of the National Commission on Farmers, on Revamping and Refocusing of National Agricultural Research, set up by the Planning Commission at the instance of the Prime Minister of India, submitted its Report to the Planning Commission in February, 2005. The Report has made recommendations for transforming the Indian NARS to meet current ecological, economic, technological and social challenges and to equip more than 115 million farm families to face the challenges in the areas of markets and climate. It has suggested ways of bringing about paradigm shift from unskilled to skilled work and from routine on-farm to value-added off-farm livelihoods. The recommendations of the Task Group are summarised below.

2.11. D.10 Strengthening strategic, applied and anticipatory research: Establish a National Board for Strategic Research in Agriculture to bring about convergence and synergy among the numerous ongoing efforts to enhance our agricultural efficiency and competitiveness and to enhance employment and livelihood opportunities in rural India and to help fill gaps in critical areas where the core competence of the country is inadequate. Declare the national institutions like IARI, IVRI, etc., as Institutes of National Importance by an Act of Parliament to provide them autonomy to become Global Centres of Excellence in research, education and capacity building and to function like the Indian Institutes of Technology. A National Council for Global Leadership in Agricultural Sciences and Education may be set up for providing overall guidance to these Centres.

2.11.D.11 In order to improve the productivity of specific ecosystems in an economically and environmentally sustainable manner, a National Participatory Research, Demonstration and Training Centre to bring together, in an integrated
manner, the available scientific institutes in relation to research, such as arid, semi arid, coastal, hill and mountain eco- systems, should be established. These should be designed on the line of the polyclinics of CSIR. A **North Eastern Cadre in the Agricultural Research of ICAR**, with an initial cadre strength of 300, to create a critical mass of women and men scientists, trained from the region as well as from the rest of India, should be created.

2.11.D.12 **A National Regulatory Policy and Structure** which can help to assess risks and benefits of agricultural biotechnology in an objective and transparent manner, based both on science and technology which is of paramount need to safeguard the environment and human health, should be developed. IPR issues alongwith SPS issues based on the principle of social inclusion, must be given due attention. Selected **National Challenge Programmes** in areas such as the impact of WTO agreement, potential change in climate, dryland farming, etc., should be initiated. Initiatives and efforts are needed in areas of value addition, non-farm employment and empowerment of Panchayati Raj Institutions to discharge the responsibilities. **Public-private partnership** should be strengthened and **Code of Conduct** to foster ethical and symbiotic partnerships between public-private structures is needed. A **National Patents Bank for Rural and Agricultural Prosperity** to enhance new technologies on the part of underprivileged sections of the rural societies should be set up.

2.11. D.13 **Professionalisation of R&D Management in Agriculture:** The ICAR headquarters should be rather a more compact technical body engaged in interdisciplinary synergistic development, implementation, monitoring and evaluation of research strategies and programmes. The research and administrative wings of the Council should be unified. About 10% of the budget of ICAR institutes should be reserved for human resource development and capacity-building through life-long opportunities for re-tooling and re-training.

2.11. D.14 The National Academy of Agricultural Research Management (NAARM) at Hyderabad should train in ICAR and SAU scientists in professional R&D management and sensitise the various functionaries in major national and international issues and
agreements such as WTO, global climate change, etc. NAARM should host a National Virtual University for Science in Agriculture to reach out the Panchayati Raj institutions and other unreached. A Creativity Index to measure the spirit of invention and innovation amongst scientists should be developed and the recruitment system should be rendered fully transparent, merit-based and assertive.

2.11. D.15 The ICAR should dynamically adopt a thorough self-introspection, participatory self-assessment and self-correcting process. In its urgently called for integration and consolidation exercise, the system may operate on a project-mode basis on the lines of The Log Frame Options used in the CGIAR which has built-in mechanisms for effective monitoring, evaluation and implementation accountability.

2.11. D.16 The fund management system of the ICAR should be improved with the help of modern technologies. Block and competitive grants and project funds should be developed with defined links between authority and accountability at every level. There should be no artificial distinction between Plan and Non-Plan funds at the Institute level. All research proposals undertaken should have sharp focus with well-defined and verifiable indicators.

2.11. D.17 Integrating Research, Extension and Development: Agricultural extension should be holistic and inclusive. Credit and knowledge flow should be synchronised in time and space. Farm Schools, Kisan Credit Cards, Agri Clinics, Agri Business Centres, etc. should be established and strengthened. An area-based rather than a single farm-based approach is needed to spread eco-farm practices particularly through the active involvement of Panchayati Raj Institutions.

2.11. D.18 All technical positions in agriculture, both at the Centre and States, should be manned by technical persons with a proven track record in agricultural transformation. A National Council of Innovative Farmers may be set up to provide a structured opportunity for sustained scientist-farmer dialogue. A National and local-level Science and Technology Alliance for Rural Livelihood Security may be formed for providing technical support for Food and Work for Employment Guarantee Programmes with
emphasis on developing skilled workforce, enhanced factor productivity, and livelihood security specially of the socio-economically-deprived people. A National Institute for the Technological Empowerment of Women and Members of Panchayats may be established. Partnership and strategic bilateral and multilateral cooperation in the research and development, especially with CGIAR system, should be strengthened.

2.11. D.19 The Swaminathan Task Group was asked to review the functioning and priorities of the NARS as a whole. Concurrently, the Hon’ble Minister of Agriculture had appointed a Committee on Reorganization of ICAR under the Chairmanship of Dr R. A. Mashelkar, Director General, CSIR to suggest the organizational and procedural changes in the ICAR with the aim to improving the research outputs of ICAR institutions and their further commercialization. The Committee submitted its report to the Hon’ble Minister in July, 2005. The Committee had the benefit of discussions with Dr. Swaminathan and Dr. V. L. Chopra (Member Planning Commission and Convener of the Swaminathan Task Group), and concentrated mostly on organizational restructuring and did not venture deep into policy and associated institutional aspects. The highlights of the recommendations of the Committee are summarised below.

2.11. D.20 The ICAR should seek to invoke its autonomous status in its true sense to enable and empower its Governing Body with greater powers in decision-making in matters of finance and human resources. Several changes were suggested in composition of the various Committees of the Council, it was suggested to have the Prime Minister of India as the President of the ICAR Society.

2.11.D.21 Several suggestions have been made for abolishing multiple layers of command and controls existing between the Institutes’ Directors and the Director General, including abolition of the existing positions of DDGs and ADGs and regrouping the activities under a few Headquarters Directors and Heads of Departments.

2.11. D.22 Institutes like IARI, IVRI, NDRI and CIFE should be granted greater autonomy while remaining an integral part of the Council. Staff Research Councils should be renamed as “Institute Research Committee”, which should play a leading role
in priority setting, monitoring and evaluation. ICAR should develop a scheme on the lines of “CSIR Jewels” scheme to provide suitable incentives to meritorious scientists as well as to encourage institutes to evolve a competitive grant system and generate income from external sources.

2.11. D.23 Existing promotion policy of scientists, which is on the pattern of Career Advancement Scheme of UGC, may be done away with. ICAR may revert back to a suitably designed promotion policy as per ARS rules, providing desired mobility of scientists between ICAR, SAU, Private Sector and International Organizations. A system for quick hire of scientists on the lines of the CSIR system may be evolved. The scientific posts should be kept out of the purview of the existing instructions under which only 1/3\textsuperscript{rd} vacancies arising in a year can be filled. The Committee strongly supports further strengthening of the National Professors and National Fellows scheme.

2.11. D.24 ICAR should develop procedures and in-house capacity for pricing of ICAR’s intellectual properties, its licensing and associated ownership rights, leading to establishment of business and market entities by ICAR institutes. The Council should take initiative for linkages with industry and private sector and have a continuing mechanism for ICAR–Industry Interface to develop Scientist–Entrepreneur Scheme. The ICAR may consider the feasibility of establishing core shared facilities with appropriate industry partners and other stakeholders.

2.11. D.25 The recommendations of the Swaminathan Task Group and of the Mashelkar Committee are generally complementary and topical. These should be critically examined and, those accepted, should be implemented by the Government without further delay.
CHAPTER III

TOWARDS AN INDIAN SINGLE MARKET

3.1.0 Introduction

3.1.1 The Tenth Five-Year Plan document has observed that the major problems faced by the trading community in internal trade are the diversity of controls exercised by multiple authorities at different levels, restrictions of inter-State and inter-district movement of goods, lack of uniformity in standards laid down by different authorities and agencies and in taxes. Pricing strategies get affected by differential tax rates and become localised. All this has led to breaking up the vast India Market into a large number of smaller regional markets. The paperwork involved in complying with the various controls, regulations and licenses, the costs involved in terms of time and resources and the inevitable corruption and malpractices that this leads to have served as a big drag on the efficiency of trading operations in the country.

3.1.2 Trade is an important sector of the economy. The share of internal trade in the Indian economy in 2001-02 [advance estimates] stood at around 13.4% of the G.D.P and employed about 36 million people, a majority of whom were self-employed, engaged in the retail and wholesale trade. It is the most important sector in the tertiary/service sector with a share that is twice the share of ‘finance and insurance’.

3.1.3 The European Community has overtime managed to bring about a Common Market for all products i.e., a market with no internal customs charges or quantitative restrictions and then a Single Market, where there are no fiscal charges at borders nor any technical barriers to trade. With a view to benefit from the international experiences, a study was undertaken by the FAO at the request of the National Commission on Farmers, through the Government of India, Ministry of Agriculture. The FAO studied the European Union Market integration experience and looked into the legislative, political and economic measures taken during the process. The European experience is documented in this study not as much to establish any direct applicability but to understand the political processes and the economic measures that led to the adoption of a common and eventually a single market in that
region. This chapter has drawn on the above report. Extracts of the above draft report from the Chapter ‘Common Market in The Federal Structure and Options for Considerations’ are annexed at Appendix–I. Since there are no internal customs duties but quantitative restrictions or prohibitions could be applied to restrict or prevent the goods from moving out of the State and movement from one State to another State could be checked at the borders and fiscal charges be applied, India could at present be considered, in European Union [EU] terminology, a Common Market. Several steps however, would have to be taken in removing the quantitative/fiscal/administrative barriers to reach what, in European Union terminology can be called a ‘Single Market’.

3.1.4 The FAO report states that one of the major impacts of removing the inter-State barriers would be the realisation of better prices by the Indian farmers as supply chain between the producer and the consumer would be reasonably streamlined. This would also benefit the consumers. The cost of agricultural products in the urban areas has a reflection of hidden costs/taxes involved in the inter-State transport. Reducing the transaction cost would help in reduction of the ultimate price paid by the consumer to some extent and improve competitiveness of Indian Agriculture.

**Box-1**

**Liberlising Trade**

“As restrictions on domestic trade are relaxed, prices stabilize across States and there are welfare gains to producers, consumers and wholesale traders at the national level. In a liberalized trade regime for both domestic and foreign trade, States make new trading partners domestically and may even prefer to trade abroad than domestically to make the best of price difference. The gains illustrated to accrue from liberalizing domestic and foreign trade are derived from small policy changes that reduce/ eliminate movement restrictions and also from reduced transportation cost.”

*Source: Jha and Srinivasan*

3.1.5 The Hon’ble Prime Minister of India, Dr. Manmohan Singh observed as under:¹

“An important commitment of our Government is to integrate the domestic market for all goods and services. The time has come for us to consider the entire country as a common or single market for agricultural products. We have to systematically remove internal controls and restrictions. We should enable direct marketing between farmers and NGOs, Cooperatives and Private Companies.”

¹ Agriculture Summit, 2005 [9th April 2005]
3.1.6 The internal barriers to trade come in the way of a large unified Single Indian Market. This deprives in great measure the advantages of trade, which leads to economies of scale and increasing returns in production. The need to remove the barriers to trade is unquestioned; the real issue however is as to how to go about in the federal system.

**Box - 2**

**The Federal Structure**

Although agriculture is a State subject, a number of major policy decisions impacting the sector are taken by the Central Government. This includes the budgetary allocations under the Five Year Plan and several Central Government programmes and policies including laying down of Minimum Support Price for selected agriculture products and input subsidies. However, State Governments retain the right to impose fiscal levies on agriculture products, which constitute a considerable source of income for them. They also have the power to fix the prices of certain major inputs like electricity and water, which are provided through public utilities. States also have considerable flexibility in providing support services to agriculture like extension services, research and development, although there are several central government programmes in these areas which are available throughout the country. Agricultural marketing is a State subject and most States have taken steps to organize and regulate the wholesale markets in agricultural products through the State enacted Agriculture Produce Marketing Committee [APMC] Acts.

Indian Constitution guarantees to every citizen freedom of trade, business or profession, but the State Legislatures are empowered to impose such a reasonable restriction on the freedom of trade, commerce and intercourse with or within the State as may be required in public interest. This implies that absolute ban on import or export of goods or quantitative restriction on movement cannot be imposed by any State Government in India. However, in practice this freedom guaranteed by the Constitution has been somewhat restricted by several regulatory and fiscal measures imposed by different State Governments. Unfortunately, whilst in Europe, custom duties or fiscal changes which have equivalent effect, are specifically banned by legislation adopted under Treaty of Rome, these restrictions cannot be done away by a legislative or administrative order of the Central Government. The States have to be persuaded or induced to remove these restrictions in order to derive the benefits of an Indian Common Market.

*FAO Report [December 2005]: Towards an Indian Common Market*

3.2.0 The Marketing Issues

3.2.1 The various issues connected with marketing of agricultural produce in India and the needed reforms for the sector have been discussed in detail in the Second Report of the National Commission on Farmers [Serving Farmers and Saving Farming- Crisis to Confidence]. The small size of operation of the farmers and the system of selling ungraded produce means that the farmer starts with a serious handicap. Further, the regulated marketing system as it operates virtually does not offer the farmers virtually any choices/options, the market charges have become high and certain cess [like education cess, infrastructure cess etc.] have been added to, the
farmers complain about lack of transparency in weighing and also in auctions and
generally about lack of infrastructure and poor treatment given to them at the market
yards, the distance from villages to regulated markets in most of the States is quite
large and with small marketable surplus and poor infrastructure, many of the small
farmers find it difficult/uneconomic to take their produce to the market yard.
Inadequate storage facilities in the rural areas and non-availability of pledge finance
leads to distress sale where spot payment means a discount of 15-20% on the price.
Some of the other weaknesses of the marketing system for agricultural produce are
listed below:

- Thin spread of regulated markets in many States and lack of development of
  the periodic village markets, which are the first contact for the farmers.
- Inadequate infrastructural facilities at the regulated markets.
- Large variations in market fee/ other charges in the different markets across
  the States.
- Variations in the entry tax/octoroi/ sales tax etc.
- Inefficient working arrangement.
- Lack of grading at the farm gate.

3.2.2 Besides the above, the complex tax structure, multiplicity of State-level
taxes, the permit system of the transport vehicles, the harassment to which the
transport operators [the truck drivers etc.] are subjected to at various checkposts and
random checking for various purposes leads to delays and increase in costs. All these
and the various Acts like the Essential Commodities Act, 1955, and the plethora of
control orders issued under it, the Prevention of Food Adulteration Act, 1954, Fruits
Products Order, 1955, Standard of Weights and Measures [Packed Commodities]
Rules, 1977, Export [Quality Control and Inspection] Act, 1963, etc make internal
trade difficult and markets fragmented. The various barriers to internal trade,
excessive paper work, various check points which the transport vehicles have to cross
causing inordinate delays and payment of bribes etc. add to the transaction cost
leading to increased price to the consumer and a lower share to the producer in the
consumer price.
3.3.0 **Barriers to Internal Trade–Problems, Causes and Suggestions**

The barriers faced in the inter-State movement of goods is summarized in the diagram below:

**Diagram:** The Regulatory Regime for Inter-State Movement of Agricultural Goods

```
Regulatory Regime: Agricultural Goods

Commodity Specific <-> Location Specific

Restriction on Flow of Commodities
- Essential
- Hazardous
- Adulterated
- Licensed
- Forest
- Endangered Species
- Others

Fiscal Related
- Customs
- Excise
- Sales Tax
- Octroi
- Entry Tax
- Toll

Restriction on Flow in Locations
- National Borders
- State Borders
- District Borders
- Municipal Limits
- Law and Order
- Bridges
- Others

Enforcement Agencies are different and the truck may be detained under any criteria
```

*Source: Debroy and Kaushik [2001]*

3.3.1. The causes leading to the above problems could be grouped under the following broad heads:

- [a] Restrictions imposed by the Essential Commodities Act [ECA] 1955/Prevention of Food Adulteration Act, 1954 etc.
- [b] Fiscal issues
- [c] Transport related
- [d] Agriculture trade related
3.3.1.0 Essential Commodities Act, 1955 and other Acts/Orders

3.3.1.1 The Essential Commodities Act [ECA] is a Central legislation to control the storage, movement and trade in a large number of commodities including food grains, edible oils, pulses and sugar. The Act was enacted with the objective of maintaining and increasing the supplies of any commodity declared as essential by the Central Government and securing equitable distribution and availability at fair prices. The Act provides the framework for rules, regulations, orders, regulating or prohibiting the production, supply and distribution, trade and commerce of the specified commodities to achieve the objective of the Act. The Act provides instruments like license, permit, price control, storage, transport, distribution, acquisition, prohibition on sale, compulsory sale [levy] to the Central/ State Governments, maintenance of records and supply of information, on which orders could be passed by the Government to achieve the objectives of the Act.

3.3.1.2 Using the powers under ECA 1955, the various Ministries/Departments have issued control orders for regulating production, sale and prices of different items. Similarly, utilizing the powers delegated by the Central Government under the Act ibid, the State Governments/UTs have issued a large number of control orders covering items such as paddy/rice, edible oils etc. As per data available with the Ministry of Consumer Affairs [2005], the number of control orders issued by various State Governments/Union Territories under food and non-food items was 182 and 55 respectively. It is understood that 41 of these were rescinded and 10 amended. The ECA 1955, and the Control Orders were relevant and issued in situation of demand exceeding the supply. The demand-supply balance and the economic environment have changed in recent years but the restrictions and controls are continuing and coming in the way of efficient functioning of the marketing system. Many of the provisions under these control orders are now outdated and have to a certain extent adversely affected the potential of private sector initiatives and consequently agricultural development in the country. Removing controls on the movement and stocking of agricultural commodities across the country could result in incentives for the private sector and cooperative sector to invest in modern storage and bulk handling facilities for a range of commodities. Private investment in these facilities is likely to increase market efficiency, reduce post harvest losses and reduce government deficits. In any case, the powers of the
Government to restrict the movement of goods out of their territory granted under the ECA, 1955, are incompatible with the principle of a single market.

**Box - 3**

<table>
<thead>
<tr>
<th>Central Order</th>

<tbody>
<tr>
<td>Despite the superficial absence of direct utilization of Control Orders, their mere presence creates uncertainty and thereby distortions. It further keeps certain powers with the food inspectors often liable to be misused.</td>
</tr>
</tbody>
</table>

*FAO Report [December 2005]: Towards an Indian Common Market*

**Suggestions**

3.3.1.3 Realizing the changing situation, the Government of India has already revised the lists of essential commodities from time to time. The number of essential commodities has come down from a high of 70 in 1989 to 15, at present. The need is to delete the remaining items also. It would be better if the ECA, 1955, was put under suspended animation for the present and revived by Government notification if any emergency situation develops, for a limited time for a specific commodity in a specified area. After watching for a few years and being satisfied that under the changed environment it is possible to tackle even emergency situations with market operations, it may be possible to scrap the Act all together. Scrapping the ECA, 1955, or placing it under suspended animation would also make various control orders issued under it redundant. However, to ensure that the States do not issue fresh control orders, the Central Government may consider the feasibility of making Central legislation to ban imposition of any restriction in the movement, stocking etc. of agricultural commodities.

3.3.1.4 Similarly the Prevention of Food Adulteration Act [PFA] 1954, Food Processing Order, Weights and Measures Act have become somewhat outdated and are misused by junior officers/inspectors etc. to cause considerable harassment to various units/establishments. It is expected that the new proposed *Food Safety and Standards Bill [2005]* could solve a major proportion of the current problems. The Bill would cover entire India and will supersede all State laws on food and food processing once it becomes a law ratified by the Parliament. The Bill clearly defines the food items and in line with the global concerns on food standards, incorporates the provisions of complete traceability on the label of the produce. However, interestingly the stress on the treaceability up to the farm-level for agriculture and horticulture is
less as compared to the processed foodstuff. In addition, the Bill proposes the creation of an apex organization, Food Regulatory Authority of India [FRAI], which would be the supreme authority for standard setting and enforcement in the food sector as against the present position where different Ministries are involved in administering different Acts/Control Orders concerning food and food processing. Furthermore, the proposed Bill, once enacted, would repeal all the concerned control orders issued by various departments, and create a streamlined framework. The specific enactments which would be repealed are listed in the Second Schedule of the proposed Bill and are as under:

Box – 4

The Prevention of Food Adulteration Act, 1954

The Act dates back to 1954 and is extremely restrictive in the category of permitted additives, which do not reflect technological options which are now available and widely used internationally. Although changes are possible, the procedure for making changes is extremely complicated and the authorities concerned have shown little flexibility in these matters. The Act is also rigidly administered in the sense that any deviation from what is prescribed, even in the matter of descriptive content of labels, is treated as an offence equivalent to adulteration, which can invite criminal prosecution. There have been instances where smudged labels have been treated as mislabeling and made a basis for criminal prosecution. In one case a label indicated the weight in “Kg.” Whereas the prescribed form under the rule was “Kg” and the mere addition of a dot at the end of “Kg” was regarded as a material deviation from the prescribed rules! Such provisions deter organise sector companies from expanding in this area while the unorganised sector, which is not policed at all, largely unaffected. We would recommend repeal of The Prevention of Food Adulteration Act.

Report on Task Force on Employment Opportunities, Government of India, Planning Commission

135
3.3.2.0 Fiscal Issues

3.3.2.1 Fiscal reforms are important in facilitating the growth of efficient trade. There exist various forms of charges/taxes on the traded commodities in India. There are considerable variations in the market charges and taxation rates across States. Sales tax is the major component of State collection, followed by State Excise and Motor Vehicles and Passengers and Goods Tax. There are differing tax rates applicable depending on the size of the vehicle. The Central Sales Tax increases the price of the goods in the consuming State in comparison to the producing State. The Entry tax by State Governments impedes the movement of goods across the State borders. Non-uniformity of laws and procedures related to taxes add to the problems of the traders.

3.3.2.2 Octroi is used as a tax levied on the products entering the territory of a city or Municipal Corporation. Whenever the agricultural products enter the area of another mandi jurisdiction, it can technically be stopped and detained for checking payment of market fee at the point of purchase any time. This acts as a major harassing force on the movement of primary commodities and inhibits free movement of goods within a State.

3.3.2.3 The multipoint sales tax system as prevailing in India has cascading affect on prices. Further, as already stated, the rates of tax are not uniform in different States and also inhibit trade on account of extensive checking of documents etc at the border check points. In November 1999, the Government of India appointed an Empowered Committee of State Finance Ministers to suggest sale tax reforms. Following the appointment of this Committee, it was decided to introduce uniform floor rates of sales tax on most of the items important for inter-State trade. However, a review of the revised sales tax rates announced by the States showed that there was no uniformity in the revised rates or categorisation of products. In some States, ‘essential commodities’ were clubbed with the ‘prohibited’ items categories for rate purposes and the highest rate of 20% was levied on items of mass consumption along with liquor and narcotics. It appeared that the decision to implement a minimum floor rate was used as an excuse to increase the sales tax rates without rationalisation of the tax structure. The above Committee also recommended the introduction of the
Value Added Tax [VAT] in place of the sales tax. The VAT has been introduced in some of the States from April 1, 2005.

3.3.2.4 The Value added tax [VAT] is a multi-point tax imposed on ‘value addition’ at each stage, which is calculated as the difference between the purchase price and the sale price allowing for the ‘set off’ on the tax paid earlier. The invoice of the inputs purchased earlier provides the claim for credit, which could be deducted from the tax liability on the sale price. Under VAT, the rate of tax is applicable at each stage. The general rate of VAT on different items as proposed by the Empowered Committee was 12.5%. 46 items have been identified as exempt items’. Gold, silver, precious and semi precious stones are to be taxed at 1% and agriculture, industrial inputs and certain essential items [a total of 270 items are to be taxed at 4%. Rate flexibility is provided for 10 local items [out of Empowered Committee’s list]. Further, petrol, diesel, aviation turbine fuel, liquor and lottery tickets are out of the VAT provisions. The Central Sales Tax is proposed to be phased out in 3 years from the second year onwards.

Box - 5

<table>
<thead>
<tr>
<th>Value Added Tax [VAT]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Since the current tax statutes are cluttered with ad-hoc and outdated rules and procedures, the ideal solution is to gradually move to uniform nation-wide Value Added Tax [VAT] is universally accepted as the most efficient form of indirect taxation. As each input going into the final product is taxed only once, this tax avoids cascading and multiple incidences and is easy to implement and monitor. A unified system of taxing domestic trade in the form of a national VAT levied and administered by the Union Government would, in one stroke, bring about harmonization and help in removing the tax on inter-State trade.</td>
</tr>
</tbody>
</table>

3.3.2.5 The introduction of the Value Added Tax initially raised several issues/problems to industry and trade. Some of these issues were the treatment relating to the pipeline stocks/documents, the long time taken by the States in release of VAT statutes and rules etc and the communication gap between the State Government and the taxpayers. All these led to uncertainly and confusion for the industry, trade and the public. The above issues were however, transitional in nature and the trade/industry and others are expected to get used to the change. It is also expected that this experience would be useful for other States when they introduce VAT. However, the continuation of the Central Sales Tax for few more years and the
impact of rate flexibility for 10 items in each State would continue to impact the possibilities of developing a Common Market.

3.3.2.6 The complex tax structure and multiplicity of State-level taxes distort the process of trade. Inter-State and Centre-State harmonisation of tax law and administrative procedures could facilitate the simplification of the tax system.

Suggestions

3.3.2.7 All possible efforts are required to introduce VAT at the earliest. Till, a comprehensive national VAT is introduced, all States should switch over to State VAT. The inconsistency in commodity classification also needs to be addressed to ensure uniformity in rates. For inter-State sales, there should be zero rate in the originating State and the destination VAT should be applied at the point of final sale. The State VAT with a harmonised rate structure should eventually replace sales taxes and other taxes like turnover tax, octroi and entry tax etc. The introduction of entry tax to compensate possible loss due to implementation of State VAT should not be encouraged. This would come in the way of a unified Common Market. The State VAT may, in due course be replaced by National VAT, once there is an agreement between the Centre and the States regarding sharing of the tax.

3.3.2.8 The octroi or any other local tax introduced by any State needs to be abolished. If however, for revenue reasons the octroi etc. cannot be abolished in all cases, at least the primary agriculture produce should be exempted from their coverage.

3.3.2.9 Another approach could be the abolition of all indirect taxes on agricultural products as a policy that would not only resolve the problem of border taxes but would also be more socially equitable. A tax on agricultural products decreases the price received by farmers and increases the price paid by consumers. As farm incomes lag behind average Indian incomes and the poorest sectors of non-farm society spend the highest proportion of the income on food, indirect taxes applied to food products are doubly regressive. Furthermore, removing internal indirect taxes on agricultural products would tend to make Indian agricultural products more competitive on export markets.
3.3.2.10 A possible measure for compensating the States for loss of revenue could be to increase the devolution of funds from the Centre to the States most affected by incomes foregone. Another suggestion particularly relevant for compensating the loss of revenue could be the increase in VAT rate on processed and semi-processed products by say 0.5% all over the country.

3.3.2.11 The FAO study has also suggested, raising the tax say on petrol, by 0.5% to generate additional incomes to compensate loss of revenue by abolition of octroi, Central Sales Tax etc. The above report has observed that the end result would benefit the financial position of the States, rather than hurting their interest, and Haryana could be mentioned as an example in this regard. The State has long discontinued the taxes and the movement restrictions on the primary commodities and has been one of the biggest beneficiaries of the new tax regime, as the tax collection rate in the State has increased appreciably.

3.3.2.12 An important step could be to change the administration of taxes so that no border checks etc. are needed. Most of the physical barriers on primary agricultural commodities at the State borders are on account of collection of sales/purchase tax or APMC cess or Octroi. Furthermore, the verification of purchase tax returns etc is another function of these posts. The introduction of uniform rates on VAT in all States and network connectivity between authorities where information regarding movement of goods from one VAT jurisdiction to another could be exchanged online may help to do away with the need of having physical barriers. It is understood that the European Union [EU] has dispensed with all border formalities without having reached the stage of full harmonization of indirect taxation. The minimum rates of such taxes have been decided at EU level, but member countries are free to set higher rates. However, to avoid trade distortion, the products for sale in another member country are sent across the border free of tax and tax is then applied for sale at the rate applicable in the member country for sale. Compensating the State Governments for loss of revenues due to removal of fiscal related barriers to trade would be a complicated issue in our federal system. This would require considerable work on the basis of data/projections etc. for a comprehensive review. It may be better if the Finance Commission addresses this issue so that the Single Market becomes a win – win situation for all.
3.3.3.0 **Transport related**

3.3.3.1 Commercial vehicles moving across borders face a multiplicity of checks from different authorities relating to road tax, license fee, payment of excise/VAT, Essential Commodities Act, forest conservation, pollution control, security etc. The transport vehicles are required to obtain ‘fitness certificate’ and pay road tax on an annual basis. These vehicles are allowed to ply only within the State covered in their ‘permit’. For movement beyond the State, the transport vehicle owner has to apply for ‘National Permit’ covering at least four States. The permit holder is required to pay the road tax and permit fee for all the states concerned. The rate of road tax in different States is different.

3.3.3.2 Further, the variation in the collection procedures across entry points even within a State is another issue. Sometimes the goods carrying trucks from the bordering districts of the neighboring States even prefer to travel by a longer route so as to avoid the additional expenditure at that particular entry-point, and have to incur increased fuel cost and undergo longer travel time in that process.

3.3.3.3 As stated earlier, there are other taxes like entry tax, octoroi, toll tax etc. In each of these cases the appropriate authority at the checkpoints reserves the right to stop and detain the vehicles, which significantly adds to the cost of transportation. The interruption of the trucks/transport vehicle could be on various grounds, and it is quite possible for a particular vehicle to face detentions on each of them, increasing the transaction cost substantially. The direct impact of these measures, coupled with the general inefficiencies in the infrastructural scenario creates a major uncertainty and hurts internal trade especially in perishable products.

**Box- 6**

<table>
<thead>
<tr>
<th>Road Transport- Problems</th>
</tr>
</thead>
<tbody>
<tr>
<td>The laws affecting the trucking industry like Motor Vehicles Act, the Motor Transport Workers Act, the Carriage of Goods Act, etc is another major problem. Smooth flow of goods carriage is hampered to a great extent by frequent stoppage of vehicles for a variety of reasons. For example, vehicle detention can be due to trucking operations or goods carried in the truck, or both. Trucking operations cover a wide range of areas, like inter or intra-State permits, road tax, load checks, local police check post, etc. But the more serious and time-consuming detention is on account of goods carried in the truck. Vehicles are frequently detained for checking essential documents, like sales tax, payment of market fee, octoroi, entry permits, etc. Besides, there are numerous other reasons under different legal provisions that can detain a vehicle, like check on the movement of essential commodities, food adulteration and hazardous chemicals etc. These checks are generally conducted by respective agencies at separate points, resulting in more than one detention. There exist flying squads or surprise checking teams other than normal checkpoints, which are empowered to stop and check the vehicle at any point within their jurisdictional limits and detain the vehicle for any violation.</td>
</tr>
</tbody>
</table>

*FAO Report [December 2005]: Towards an Indian Common Market*
3.3.3.4 The FAO report states that the cost of importing grains from Thailand to the bordering States is cheaper than transporting the same from another State of the country. Even the cost of importing from the US ports to India [select ports] is cheaper than the road transport of grains from Punjab to Andhra Pradesh. It establishes the abnormally high transport cost one has to incur in the country.

**Box - 7**

**High Transport Cost**

The extent to which the inter-State barriers inflate cost further becomes obvious from the Table below. It is observed from the table that the cost of importing grains from Thailand to the bordering States is cheaper than transporting the same from another State of the country. Even the cost of importing from the US ports to India [select ports] is cheaper than the road transport of grains from Punjab to Andhra Pradesh. While the analysis is exploratory in nature, it clearly establishes the abnormally high transport cost one has to incur in the country.

*Ramesh Chand [2002]*

3.3.3.5 Inspite of the high cost of road transport [in absence of any suitable alternatives], about 65% of the goods haulage is by roads. The road length in India increased by over six times between 1951 and 1996-97, but the status of road connectivity is rather poor. Another issue is the cartelised nature of the road transport industry. New entrants in the business are not much welcomed. It is reported that there is no undercutting among the top 100 truck owners leaving virtually no room for competitive price negotiations. Medium and large truck operators [above six trucks] account for nearly 87% of the business. Most of the truck operators are running their business as ‘family concerns’.
Suggestions

3.3.3.6 In order to ensure that reforms in removing the barriers lead to gains to the farmers, and are not largely appropriated by transport operators, the Government may closely look at the road transport operations and take suitable measures to curb cartelisation and make room for easy entry of farmers/farmers’ groups and other individuals in this sector.

3.3.3.7 The removal of the inter-State barriers would facilitate the internal trade on one hand, while indirectly facilitating the foreign trade on the other. This would lead to welfare gains to all parties concerned including the farmers, processing and exporting firms as well as the final consumers.

3.3.3.8 To simplify the arrangements, it may be suggested that a uniform amount may be charged for the National Permit and the permit holder may be allowed to ply the vehicle anywhere in the country. Similarly, the system of annual fitness certification and road charges may be replaced by a lifetime charge assuming around ten-years life for a transport vehicle. For plying the vehicle beyond the above limit, the vehicle may be subjected to an annual fitness certification and payment of fee etc.

3.3.3.9 But for revenue consideration, the concept of ‘National Permit’ has no other value. The government could also consider doing away with it all together.

3.3.3.10 All checks [other than those for security reasons] may be given up or at least integrated under one window. Use of computers may be encouraged to minimise the detention time at various checkpoints. This may also increase the revenue collections.

3.3.4.0 Agriculture Trade

Agriculture Produce Marketing Committee [APMC] Act

3.3.4.1 The wholesaling of agricultural produce is governed by the Agricultural Produce Marketing Acts of various State governments. Once a commodity is notified, the APMC Act makes its transaction mandatory in the regulated market. Various Government Committees noted that this monopoly, introduced with the objective of benefiting farmers, is actually harming them. Although market committees may legally
be considered as a corporation [or Local Authority], they function virtually as a
department of the State government. The market fees charged on value of produce sold
[known as the Mandi tax] do not reflect the actual operation and maintenance cost of
the wholesale market but seen as another tax on agricultural commodities. Apart from
the mandi tax [usually two percent in most of the States], there are several other charges
applied on the products entering the regulated market yard. The major charges among
this category are usually rural development cess [2 percent], infrastructure cess [2
percent], education cess [0.5 per cent] etc. While the actual utilization of the collected
funds for these purposes is somewhat questionable, it is the farmer who has to indirectly
bear the entire burden, as the trader takes account of these transaction charges while
making the bidding. The State governments usually find these mechanisms a major
source of extra budgetary income, outside the purview of audit. Hence, very often, they
tend to be used as discretionary funds by the political masters. The APMCs have also
generally failed to provide adequate infrastructure at the mandis. The focus of the
APMCs has been on regulation and not development of markets for the local products,
introducing grading and encouraging local processing etc. The APMC have also not
played any significant role in bringing better market information to the farmers.

3.3.4.2 Direct marketing could enable the farmers to sell their produce to the
processors or bulk buyers at lower transaction costs and maybe at better prices than
what they get from intermediaries or from the wholesale markets. However, the
APMC Act in most of the States does not allow direct buying by processing
industries, exporters or wholesalers. Although this requirement has been waived on a
case-by-case basis in some States under pressure from the industry, the market fee
still has to be paid even though the produce may not enter the APMC yard.

3.3.4.3 Multiple collections of mandi taxes is another problem, as Market
Committees insist on collection of market fee again when the product comes from
another Market Committee jurisdiction. If a product comes from outside the State,
then the seller has to pay the market fee again, even if he has paid it in the State of
origin. This procedure of double taxation needs to be removed.

3.3.4.4 The monopoly of APMCs has meant that the private sector including
cooperatives have not been able to contribute in establishing and developing mandis.
The provision of the APMC Acts in different States requires modification to create a
lawful role for the private sector in the marketing development. The inter-Ministerial Task Force on Agriculture Marketing Reforms, which gave its report in 2002, has observed as under: “High investment and entrepreneurial skills are required for creation and management of agriculture marketing infrastructure. The situation of control by the State has to be eased to facilitate greater participation of the private sector, particularly to engender massive investments required for the development of marketing infrastructure and other supporting services. Investment requirements for the development of marketing, storage, cold storage infrastructure in the country during the Five Year Plan period has been estimated to the order of Rs.12,230 crore”.

Suggestions

Amendment of APMC Act

3.3.4.5 The regulatory marketing system introduced after independence was necessary at that stage to ensure transparency in trade in agricultural commodities and to ensure fair price to the farmer. But the working of the marketing committees has been questioned at times on various grounds including lack of transparency in operations. Farmers often express that the regulated markets are not friendly to them and the traders/petty officials exploit them. In order to improve the transparency in the operation of the APMCs, it should be made obligatory for them to publish the daily arrivals, maximum and minimum prices and the balance of stock available. Availability of this information on the Internet for all APMCs on a day-to-day basis could be the first step to develop an all India market. The monopoly of the APMCs in establishing and managing agriculture produce markets has meant that the private sector including cooperatives have not been able to contribute towards developing and building up marketing infrastructure in the country.

Box – 8

Amendment of APMC Act

The operation in APMC creates monopolies of the State Marketing Board/Market Committees in regulation the wholesale market by not allowing direct marketing, often leading to cartelization of a few brokers or arthiyas and non-transparency in price setting to the disadvantage of the farmers. The monopolistic operation of the market committee also acts as a disincentive to private sector in setting up processing units for value addition, as they do not have direct linkage with the farmers, which would otherwise help them in getting raw materials of assured quality and quantity. The policy framework should give farmers the liberty to freely market their produce anywhere including direct marketing to processors or other buyers without paying any market fees. However, in case they want the facilities of the market yard, they have to pay a service charge, which should be sufficient to cover the operation costs of the market committee.

FAO Report [December 2005]: Towards an Indian Common Market
3.3.4.6 The need for amendment of the APMC Act has already been discussed in the National Commission on Farmers second Report ‘Crises to Confidence’ released in August 2005. It may be repeated that the Ministry of Agriculture, Government of India have already formulated a Model Act on Agricultural Marketing incorporating the necessary reforms and circulated it among the States for suitable amendments in their respective APMC, Acts. The model Act basically follows the framework of the existing APMC Act with some modification and additions to facilitate direct marketing, entry of private sector including cooperatives in developing markets and contract farming etc. As per the Model Act, the waiving of market fees would only apply to specified produce sold under contract farming; direct sale would still be subject to market fee; direct buying from a farmer’s premises would require a license from the State Government etc. It appears that the Model Act would require a relook if all barriers to internal trade were to be removed.

3.3.4.7 With the increasing quantum of market arrivals, the need is to promote alternative and mega markets especially near the big cities and metropolitan towns outside the purview of the APMC Act.

3.3.4.8 If however, the taxation on primary products is discontinued, the APMC Act and marketing committee checkposts at the State borders would become redundant. The Government needs to abolish market fee on primary agricultural commodities altogether and levying of charges for various services like loading, unloading, weighing etc. in the APMC yard and replace it, by one consolidated service charge for use of the market infrastructure. This would bring in greater efficiency. In case the government finds the removal of market tax not possible immediately, it may be phased out over a period of two to three years, but the additional taxes like ‘Rural Development cess’, Infrastructure cess, and ‘Education cess’ have to be discontinued at the earliest. Furthermore, allowing private players including cooperatives to establish private mandis will be a major step in providing an alternative to the farmers and could lead to higher return to the farmers. The private players in most of the cases are selling processed agricultural products to the final consumers and therefore prefer to have assured supply of primary products. The coming up of pre production sale agreements loosely referred to as ‘contract farming’ is a significant development for Indian agriculture as it is expected
to enhance the level of investment in primary sector and boost productivity. Amendment/suitable restructuring of APMC Act would facilitate this trend further.

3.4.0 **Supporting Measures**

3.4.1 A host of supporting measures would be needed to ensure that the benefits of the Indian Common Market reach the farmers and the consumers [farmers and their families in India also form a very large percentage of the total population] and are not appropriated largely by the traders/truckers etc. Some of the supporting measures are discussed in the following paragraphs.

3.4.1.0 **Standardization and Harmonization of the Quality Standards**

3.4.1.1 The technical standards prevailing across the States are quite divergent and confusing at times. The prevailing scenario is in a way responsible for the current level of lower internal trade. In addition, the regional confinement due to diversity of standards often does not allow the players to enjoy the economies of scale. Furthermore, in coming years organized retail trade is going to be important in the country, and therefore there is need to ensure harmonization of the various prevailing standards across Indian States. Given the wide difference in the use of standards as well as selection of units prevailing in the country, the harmonization need to be introduced at every stage [e.g. – grading, packaging] to facilitate quick transaction. *Apple* is a fair example in this regard, where the level of standardization in the country is quite comprehensive, explaining the intensity of inter-State trade in it all over the country.
Box - 9

Horticulture

Horticulture products being high value have chance of increasing farmers’ income and generally improving the nutrition contents of the food basket. The Government of India have launched the National Horticulture Mission [NHM] to double horticulture production to 300 million ton by the end of 2011 from the level of 152 million ton in 2000. To get the optimum benefits from the NHM, it would be essential to ensure that the farmer gets a fair return in the form of increased income by increased productivity, reduction in post harvest losses, generation of value addition and shortening the supply chain in the marketing system. A national ‘common or single’ market would require countrywide cold chains and improvement in processing and transportation facilities. The barriers to internal trade, particularly in the transport sector due to poor/inadequate road connectivity, slow movement of goods, and delays at check posts etc. need to be removed specially for the perishable commodities. There is also a need to harmonise various laws/regulations for the food-processing sector to encourage increased private sector investment and improved quality of products. The Task Force on Employment Opportunities, Government of India, Planning Commission had stated that there were six Ministries in the Government of India [the Ministry of Agriculture, Rural Development, Health and Family welfare, Food Processing Industries, Commerce and Civil Supplies, Consumer Affairs and Public Distribution], which were administering various Acts/control orders concerning food processing. The large number of Acts/Control Orders, their interpretation etc. and the fact that different ministries handle these, make the compliance extremely difficult. Direct marketing by the producers to the consumers and development of specialized markets for fruits near the bigger towns/cities could help in improving farmer’s share in the ultimate price paid by the consumers.

3.4.2.0 Policy Support in Creation of Farmer Communities

3.4.2.1 While the removal of fiscal and procedural barriers would facilitate the movement of primary products with greater ease, there is a need to analyze its consequences on the return to the farmers. While the streamlined movement, absence of taxes and presence of private sector is likely to enhance the return to them, the major proportion of the lower transaction cost could however, still be appropriated by other players [traders, private players etc.]. Furthermore, the dominance of the truck union over road-route makes the possibility of large gain by individual farmers unrealistic. It seems prudent that the government should encourage the formation of producer enterprises in various forms all over the country so that a section of the farmers can themselves reap the benefit of the lowered transaction cost by sending the products to various parts of the country. The need is to give the power of scale to the small farmers both in production and post harvest operations to enhance their incomes. In the first report of the National Commission on Farmers ‘Serving Farmers and Saving Farming’ need for organisation of small farmers horticulture, cotton, poultry, aquaculture and other ‘Estates’ to facilitate delivery of inputs and confer power of scale to the small growers in production, post harvest and marketing was emphasized to increase their productivity and incomes.
3.4.2.2 There is also need for forming larger groups of farmers engaged in the production of higher quality products for specific markets within specific agro-climatic zones. There is not much evidence that agro-processing and marketing enterprises have interest in procuring raw materials from small farmers unless the crops are highly intensive or belong to niche groups and certain labor intensive vegetable crops that need frequent harvesting [e.g. - baby corn, gherkins, mangetout and sugar-snap peas].

3.4.2.3 The realization of economies of scale in procurement, technology adoption and marketing is better performed by producer groups. From the supply side it is not easy for value addition enterprises to work with a large number of small farmers, which involve problems of product uniformity, product traceability and variation in cropping programs leading to a greater management input and raw material procurement cost. In a number of countries, governments encourage small farmer involvement in agro-enterprises. The motivation for the enterprises could come from government offering tax breaks and concessions, a supporting bureaucracy or relaxing zoning laws when companies are establishing new processing units or retail outlets, Government support services related to strategic crop production, specialization etc. Consequently, the small farmer gains access to the market, the consumer welfare increases substantially, and the processors and packing houses have a focal point, for example, a producer group or association to work with.

3.4.2.4 The farmer group operation would facilitate requirements for quality and traceability for exports, which is currently not always possible with numerous small holdings. In farmer communities, due diligence will occur through proper record keeping and monitoring on the farm during the production process and with strong linkages within the supply chain.

3.4.2.5 The formation of farmers’ collectives would further facilitate crop specialization in clusters. Farmers in specific agro-climatic zones with comparative advantage for certain crops or products could obtain comparative and competitive advantage by crop specialization in conjunction with other farmers in the location. The three main reasons for specialization could be [i] the limited and finite resources in the area could be channeled to work with the farmer groups on those crops or products; [ii] processors and industry would become concentrated and established in
the production zone, if the region could provide sufficient volumes of product and continuity of supply to make a processing enterprise viable; and [iii] farmers could better manage a particular crop or a group of crops in order to achieve specialization.

3.4.2.6 Producer groups and associations organized as agribusiness enterprises could exercise either of the following product management system – [i] the growers or farmers become an integral part of the supply chain; [ii] producers who earlier were competitors, work together, with that particular product passing through a farmer marketing group that has the responsibility for the category; [iii] any marketing group has to commit to supply two to three outlets and form a working relationship based on the principles of partnership; [iv] the decision regarding type of product variety to grow will be determined by the farmer enterprise group on the basis of agro-climate, resources available, consumer and market studies; and [v] the growers and producers in charge of the programme take all the risks in the management of that product.

3.4.2.7 The proposed enterprises could take various forms, e.g. agricultural cooperatives, commodity-based collectives etc. The agricultural cooperatives in India have so far suffered from various institutional drawbacks [poor management quality, excessive government control etc.] and are not a universal success. The government may provide start-up capital to these producer enterprises through institutional support policy [credit in easy terms] as well as technical support [opening training centres to provide management skills to the village-level select representatives from the cooperatives] to avoid the potential problems, National Dairy Development Board being the best example of the success story.

3.4.3.0 Credit Policy

3.4.3.1 There is also a need for development of suitable credit policy framework for ensuring benefits to the farmers from a nationwide common agricultural market. The main motive for creation of the Common Market is to increase the internal trade in agriculture, improvement in productivity and move to high value agriculture. Given the resource-constraint of the average Indian farmer, it is unlikely that they would be able to increase investment in land or productivity on their own. In that case, the gains from the creation of the Common Market could bypass a major segment of the farming community, and the purpose would be defeated. The government may formulate a much stronger credit policy, and implement it effectively. The National
Bank for Agriculture and Rural Development [NABARD] as the development financial institution for agriculture will be required to play an important role in this regard particularly in financing the farmer associations/groups/organisations. Financing of new agri-business opportunities would require development approach and a sound knowledge of agri-enterprises. The linkages between credit and marketing will require to be strengthened and need based new credit products developed.

3.4.3.2 **With increase in trade, the development of instrument based secondary market of negotiable warehouse receipt system would become important to provide liquidity in the marketing system.** The banks are presently reluctant to provide loans against the warehouse receipts issued by the Central Warehouse Corporation when the holder is not the person in whose favour the receipt was originally issued. Transferability of the warehouse receipt is limited but for the fact that the original owner cannot transfer it to another person without clearing the bank’s dues. While the State warehouse Act provides that a warehouse receipt is transferable by endorsement and shall entitle the holder to receive the goods specified therein on same terms and conditions on which the person who originally deposited the goods would have been entitled to receive. Due to the above shortcoming the usage of the warehouse receipt, as a financial instrument has not picked up.

**Box - 10**

<table>
<thead>
<tr>
<th>Lending Against Commodities</th>
</tr>
</thead>
<tbody>
<tr>
<td>Banks do have a facility for lending against commodities. However, this potential has never really been realised in the Indian context as lending against commodities is considered to be a high-risk area as this sector is considered to be one of the defined ‘Sensitive Sector’ in the economy and put on par with capital markets and real estate lending. The bank is firstly not sure of the creditability of the warehouse owner and its managerial ability. Instances are cited where the warehouse owner has disappeared or misappropriated the commodities stored in the warehouse. Cases of fraud have been experienced in the past, which has made banks distrustful of the same. Secondly, the bank is not internally equipped to evaluate the goods stored in the warehouse and is uncertain of the quantity and quality of the goods lodged therein. Thirdly, there is doubt regarding the longevity of the goods. Agricultural commodities largely are prone to deterioration in quality as they are stored for longer periods. Hence, even though the goods are pledged to the bank, in case of default the bank may not be able to realise the value due to the deterioration in quality of the farm produce. Lastly, authenticity of the warehouse receipt, which has been pledged by the farmers, is sometimes in doubt. Therefore, given the high risk attached to this kind of lending, banks have preferred to keep away from such credit and have also tended to charge high rates of interest on such loans. This has become an even more serious issue in light of the stringent capital adequacy norms that are to be implemented under the Basle II Accord where risk weights are to be adduced having regard to the level of risk in each lending structure as reflected by its credit rating.</td>

*Source: P.H. Ravikumar, Trading in Dematerialized Warehouse Receipts: Opportunities for Banks and Other Financiers*
3.4.3.3 The need is to establish a more secure system. If there were prescribed norms for accrediting the warehouses and they could provide certification about the quality and quantity of goods, the receipt would have better transferability. However, this presupposes availability of acceptable grading norms and standards of goods kept in the warehouse across the country and the reliability of the certification system. The goods have also to be stored according to grades and standards so as to create market segmentation. Further, the warehouses must meet the financial standards so that the banks could trust these.

3.4.3.4 The crucial issues are evolving of commercially acceptable quality standards in respect of different commodities, the accrediting agencies working efficiently to improve confidence, having arrangements for gathering appropriate market intelligence about pricing and analyzing it for linkage with quality standards of the commodities accepted for storage.

3.4.4.0 Food Security Related Concerns

3.4.4.1 The argument in favour of retaining the barriers on inter-State trade in agriculture is sometimes based on ensuring food security. The idea is that, whatever be amount of foodgrain production by a particular region [State], it has to ensure a control on its movement so that it does not experience a shortage in case of bad harvest. Deficient regions could be particular about this argument. However, the argument is based on a wrong premise. Free and smooth movement of goods could ensure better food security. India’s poorest regions are districts characterized with poor infrastructural facility and irrigation networks.

3.4.4.2 The viability of this ideology seems quite untenable, as seen from the findings of various committees. Most of Indian States are deficit in foodgrains, and therefore there is all the more need to ensure free flow of primary products. Stating the growing cereal deficit in the country, the Committee of Long Term Grain Policy [2002] has rightly cautioned against the potential problem in the backdrop of which ensuring free movement of primary products is all the more necessary.

3.4.4.3 Local controls usually put a downward pressure on the prices received by the farmers, and the higher price, in such situations, is entirely appropriated by the
traders. Given this scenario, there is all the more reason to believe that removal of the movements on agricultural products will enhance food security and definitely not reduce it.

3.4.4.4 Certain aspects related to food and nutrition security were discussed in the Second Report of the National Commission on Farmers – Serving Farmers and Saving Farming - Crises to Confidence. **Access to food grains is related to the purchasing power of the population and the nature of public distribution system that is prevalent.** The focus has therefore to be increasing the incomes of poor and improving the implementation of the public distribution system. However, in areas, which are difficult to access, in addition to the above, the Government may also support the establishment of Community Food Banks/Grain Banks to improve food security of the poor.

3.4.5.0 Commodity Forward Trading

3.4.5.1 While India has a long history of futures markets in agricultural commodities, during the mid sixties to 2002; forward trading was banned for many commodities. The Government of India have since permitted futures trading in many commodities including wheat, gram, coarse cereals, Kharif pulses, peas, rice, paddy, sugar, khandseri, gur, coffee, potato, turmeric, cotton, raw jute, major edible oils, oilseeds and their cakes, rice barn, chillies, cloves, ginger, rubber, pepper, silk etc. Three national level exchanges and 21 regional exchanges are providing commodity forward trading facilities.

3.4.5.2 Forward and futures markets enable sellers and buyers to reduce uncertainty and consequent risks through price discovery ahead of actual production. It helps in price stabilization by damping the peaks and moderating the laws, leads to an integrated price structure throughout the country and ensures balance in supply and demand throughout the year. By aligning their functioning with spot markets, the forward/futures markets can work as a tool to handle complex situation arising from good and bad harvest through stabilising supplies prices. For the processors the facility helps to hedge price risks, avoid storing of goods and minimise the carrying costs is critical. **An orderly functioning forward market is essential for an efficient working of the markets and providing liquidity.**
3.4.5.3 At present the Forward Market Commission [FMC] regulates the forward markets in commodities. The FMC, which for decades was entrusted with the objective to curb forward traders, now has the job to develop and regulate the Commodity futures market. The Hon’ble Union Agriculture Minister has recently [while inaugurating the Fifth National Conference of Commodity Exchanges at Mumbai on 17 December, 2005] talked about strengthening and restructuring the Forward Market Commission and making it autonomous and independent regulator. It is reported that the proposed amendments to the Forward Contract Regulation Act also provide for setting up a Forward Markets Appellate Tribunal on the lines of Securities Appellate Tribunal [SAT] set up under Securities and Exchange Board of India [SEBI]. The steps for improvement in transparency in the operations of the Commodity Forward Markets are welcome particularly in view of the fact that commodity futures market was discouraged [near total ban] for many years and should now be developed to function in a very orderly and transparent manner. The Government may also consider permitting ‘options contracts’ under the forward trading in commodities for risk containment. However, option trading could also be used for purely speculative purposes.

3.4.6.0 Market Information

3.4.6.1 One of the major problems in India agriculture is the lack of timely and correct information to the farmer. The farmers and their groups/association/structure not only require information about the prices but also about the arrivals during harvest and pre-harvest period, stocks, exports/imports, trend in production, forecasts of production/prices etc. to take full advantage of price variations. Such information is essential for commercial operations. The Ministry of Agriculture website provides the data on price trends for major commodities, but at the village level such information is not always readily accessible. The above website would require to enlarge their functions. The farmers and their groups would also require information about the prices, availability, and qualitative aspects of various inputs for modern agriculture. The APMCs/ State Agriculture Market Boards could have played an important role in this area. However, it has not happened so far. These structures should see a business opportunity in providing these information to the farmers.
3.4.7.0 **Infrastructure Needs**

3.4.7.1 The infrastructure constraints could be a major issue in realizing the full benefits of a large all India market. The inadequate spread of regulated markets in many States, lack of basic facilities like electronic weighing machines, price display boards, public address system, electric lights, banks, security posts in many markets, inadequate connecting roads, storage facilities including cold storages etc are serious bottlenecks in developing a farmer centric marketing system. It is hoped that the amendments to the APMC Act would attract private sector participation and would facilitate creation of much needed infrastructure.

3.5.0 **Conclusion**

3.5.1 The Indian economy has moved away from shortages and scarcities. The agriculture sector has the potential for creating greater job opportunities and generation of incomes. However, the need is to first unchain the sector. Various Acts/orders etc., which were enacted to regulate stocking/marketing/movement of agricultural produce and generally to safeguard, the interests of the farmers and the consumers [check against dishonest business practices] appear to have outlived their utility. The APMC Acts, the Essential Commodities Act and various orders/enactments issued there under, the prevention of Food Adulteration Act, the highly complex tax structure, different rates and procedures under the Central Sales Tax, Octroi, Entry Tax in different States has made the compliances of these laws difficult and has led to development of fragmented markets. Further, the taxes at State and local level are on a cascading basis. The transport of goods across the district/State boundaries is slow and time consuming. The goods carriers could be detained at border posts for any number of reasons and for any length of time. The junior officials and others manning these checks are not too reluctant to accept ‘bribes’. All these lead to higher costs and inefficiency in trade.

3.5.2 The Government of India have already initiated various steps in the right direction. As regards the regulatory framework, the number of Essential Commodities under the Essential Commodities Act have been reduced from 70 in 1989 to 15 at present, the Government of India have circulated a draft model APMC Act to the State Governments with a view to facilitate necessary amendments to the APMC Act. The draft model APMC Act provides for enabling private/cooperative sector to
establish and operate agricultural marketing infrastructure and supporting services, 
direct marketing of agricultural commodities by farmers etc, permitting contract 
farming, introducing single point levy of market fee etc. However, the draft model 
Act would require a relook to be more effective in the context of removing the 
barriers to trade. The Government have also taken important steps in introduction of 
Value Added Tax [VAT] etc.

Box-11

**European Experience**

Looking at the European Union [EU] experience in developing a Single Market, it would 
appear that the task accomplished was quite difficult as compared to the task ahead in India. 
The European Community [EC] is a Union of independent nations with no central government 
or common currency. These countries also had different agricultural policies, different tax 
rates, different price support systems and level of support prices. The level of support prices 
was the most contentious issue with the countries having high support prices insisting that the 
price level should be near their support price while the EC wanted it to be near the level, which 
could be remunerative to the efficient producers. The other aspect is that all countries did not 
come together at the same time; rather the countries have joined slowly and mostly in batches. 
Six countries signed the Rome Treaty in 1957 and the latest to join was a batch of 10 countries 
[8 from Central and Eastern Europe, Cyprus and Malta] in 2004 taking the number of 
members to 25. Since the EC had decided in 1985 to become a Single Market by 2002, the late 
entrants [after 2002] did not get even the transition time to harmonise their technical and 
health standards.

*FAO Report [December 2005]: Towards an Indian Common Market*

3.5.3 Much work is still required to be done to remove the bottleneck in the 
transport sector, due to the multiplicity of commodity specific restrictions [essential, 
hazardous, adulterate, licenced, endangered species, forests] the goods carrier could 
be stopped at many points [State borders, district borders, municipal limits, bridges 
etc] and also regarding verification of payments regarding the Central and State Sales 
Tax, Entry Tax, Octroi etc. causing long delays and considerable harassment. As 
stated earlier, if this aspect of tax administration could be changed some of the 
harassment of the transport operators would be eliminated. The aspects regarding 
fitness certificate of the vehicle, issue of national permit, payment of road tax etc. also 
need simplification. The issue here is not so much of revenue losses but of the 
mindset and the vested interests of a large number of inspectors/junior officers and 
others who thrive in such situations. The need is to build a national consensus and 
move forward. A road map to build over the developments so far made is required. 
As stated earlier the transport barriers/bottlenecks have not so far attracted adequate 
attention of the Government for corrective measures. The implementation of the
reforms/changes, which do not have revenue implications or the impact is likely to be only marginal, need to be taken up first. The legal reforms i.e., changes in the APMC Acts, relook at the Essential Commodity Act and other related Control Orders and the Acts etc. are already under consideration and need to be expedited. The need is for deepening and broadening of the general consensus and a strong political and administrative will to move on.

3.5.4 Loss of revenues to the States is not an easy issue to tackle particularly in a federal set up. However, the progress being made in introduction of the Value Added Tax [VAT] is indicative that consensus could be arrived at in the larger national interest though it takes time. The Government of India may consider requesting the Finance Commission to address this issue for the common benefit of all.
Appendix-I

Extracts from Chapter 5 of the FAO Report [December 2005]:

Towards an Indian Common Market

Common Market in a Federal Structure and Options for Consideration

1. A common market for agricultural products means a market within which there are no institutional or legal barriers to the free circulation of such products, so that producers or traders can sell with the same freedom across state borders as he can within his own state. The analogous concept in the EU is a single market (because the EU used the term “common market” to refer to the stage in its development when there were no longer any customs duties or quantities restrictions in its internal trade but there were still fiscal charges and non-tariff barriers). In India at present there are no internal customs duties but certain fiscal levies and administrative orders are sometimes applied to restrict or prevent movement of agricultural products from one state to another, which have led to erection of check posts at borders. So India is close to being what, in European terminology, would be called a common market but has several steps to take to reach what, in EU terminology, would be called a Single Market.

2. In a common market that applied to all goods there would be no need or justification for the existence of customs officers at state borders and all such customs posts would be closed down, as has happened in the EU. The mandate for this study was limited to the establishment of a common market for agricultural products and we have not, therefore, examined the case for, and means of establishing, a common market in India encompassing all goods. Nevertheless, we observed that a comprehensive common market for good would have advantages compared with a common market confined to agricultural products both for the Indian economy as a whole and agriculture. For the economy as a whole, it would improve efficiency by encouraging the optimum allocation of resources, thereby raising GNP. For agriculture, it would allow the easier “import” of agricultural inputs into states that are in deficit. And the closure of customs posts would ensure that the objective of a common market for agricultural products was not circumvented by ingenious devices like taxes on non-agricultural products that are used in transport of agricultural products, like the tax on bags used in the transport of apples referred earlier.
Furthermore some of the accompanying measures that can be taken to make a common market work more effectively, in particular road construction and improvement are better justified as part of a comprehensive common market than of a common market confined to agriculture.

3. Analogies between the EU and India have to be interpreted with caution as the two are very different entities. India is a single nation, albeit with a form of federal constitution that provides separate powers for the Centre and the States and India is a developing country, and like most other developing countries, has a very large proportion of its population engaged in agriculture. The EU is a union of independent developed countries that have agreed to pool their sovereignty in certain areas. However, there are certain similarities. In the EU some matters are dealt with collectively at the EU level and others remain at the competence of the member states or regions within the member states. In India, the Constitution prescribes sharing of power between States and Centre in certain subjects in the Concurrent List but allows exclusive jurisdiction to each in the other subjects, which are well demarcated.

4. The original 6 members of the EU came together for both political and economic reasons. Politically they wished to move towards greater unity, in order to bind up the wounds of the war and to remove the risk of a new one. Economically they hoped that by trading freely between each other they could create wealth. It was recognized from the outset that a common market was not consistent with the retention of separate agricultural policies and that these should therefore be replaced by a single common policy. For some (e.g. Germany) this was seen as the “price” to be paid for having a common market in other products. For others (e.g. France) it was an advantage to be gained in return for providing free access to their markets for other products. The various countries that have joined the EU since it original foundation have similarly felt drawn to do so for a mixture of political and economic reasons. And, as was the case with the original Six, some see the CAP and the support it provided for farmers as an additional incentive to join, whilst for others it is a cost to be paid in return for the other advantages, political or economic, of being a member. For example, of the countries that joined in 1973, it was seen as an advantage by Ireland and Denmark and a cost by the UK. And the fear that the CAP would provide a lower level of support than their national policy was one of the factors in the
decisions of Norway and Switzerland to not to join the EU. Although, however, different EU members see the CAP as a cost or a benefit, up to now, all have accepted that a common market does imply the need for most powers relating to agricultural support to be exercised at EU and not national level. However, member states can still take their own decisions in relation, for example, to agricultural extension services or research, (although there are also some common research projects) and they have some discretion on the precise way in which some EU wide measures are applied.

5. As for the impact of the market integration on farmers in the EU the setting up of the common market in the 1960s necessitated the removal of national price support policies and the establishment of a Common Agricultural Policy [CAP] with common support prices. The same is true of subsidies. The move from a Common Market to a Single Market in 1993 did not, of itself, necessitate any change in the level of common support prices or of subsidies but it happened to coincide with major changes in both that were being introduced, for other reasons, at the same time and whose impact on farm incomes was clearly positive. This makes it impossible to identify the impact on incomes of the reduction of transaction costs that arose from the ending of border formalities. At a theoretical level, the reduction of transaction costs in international trade can be compared with the reduction of a tariff. In both cases the impact will be to facilitate the flow of goods from a surplus to a deficit countries, which will tend to increase prices in exporting countries and reduce them in the importing countries. So the reduction in transaction costs will have had this kind of impact on market prices (which can differ significantly from the support prices fixed under the CAP) within the EU. The fact that prices for some farmers will have been increased and those of others will have been reduced does not mean that the benefits for some farmers were exactly offset by the losses for others. Trade is not a zero sum game and can be mutually beneficial. For example, Spain frequently has a deficit of feed grains, which is made up by imports from other EU member states, in particular France and the UK. A reduction in transaction costs on this trade will have been of direct benefit to French and UK cereals farmers but it will also have benefited Spanish livestock producers for whom feed grains constitute an input cost."

6. More generally, the common and then single markets should have created wealth through their impact on the non-agricultural parts of the economy where, with
no common support price system, the principle of comparative advantage has applied more freely. To the extent that this has improved the overall economy by comparison what would otherwise have been the case, it will have boosted the employment prospects of people who have left the agricultural sector (or chosen not to enter it) and this will have had a favourable impact on the incomes of those who remained in the farming sector.

**Regulatory Concerns**

**Essential Commodity Act**

7. The *ECA* was introduced during a period when India was not self-sufficient in agriculture and controlling the movement and storage practices acted as an efficient check against dishonest business practices. However, given the fact that India has now created a respectable buffer stock of food grains against any disaster, thanks to the operation of the FCI, there is scope for re-looking at the actual utility of the provision. Several government committees (e.g. – Mid-term review of Tenth Plan, Planning Commission) as well as key policymakers have at times expressed concerns over the provision. There is reason to believe that the law has outlived its utility and is only contributing to the rising transaction costs. Although in the last few years both the State and the Central Governments have taken number of steps to reduce the rigors of the ECA and the number of commodities covered by it has been drastically cut down, the government still retains the right to bring any commodity under its purview, if need be. Out of the 15 commodities still kept in the list, 11 are related to agricultural products. The mere threat of potential Government action keeps the private sector participation in storage, transport and processing at a low level. It also bears consequences on verifications made at the inter-state borders on movement of goods.

8. The powers for states to restrict the movement of agricultural products out of their territory granted by the ECA are incompatible with the principle of a single market. They may have served a purpose in helping to preserve local food security but at the cost of reducing food security for India as a whole. For these reasons the provision should gradually be phased out.
Amendment of APMC Act

9. As regards the collection of market fees through the APMC Act, it still continues to be a major hurdle on the free movement of primary agriculture products from not only between States but also even within the States from one market area to another. As already stated, it sometimes results in double taxation of the same products. Moreover, its operation creates monopolies of the State Marketing Board/Market Committees in regulating the wholesale market by not allowing direct marketing, often leading to cartelization of a few brokers or arthiyas and non-transparency in price setting to the disadvantage of the farmers. The monopolistic operation of the market committee also acts as a disincentive to private sector in setting up processing units for value addition, as they do not have direct linkage with the farmers, which would otherwise help them in getting raw materials of assured quality and quantity. The policy framework should give farmers the liberty to freely market their produce anywhere including direct marketing to processors or other buyers without paying any market fees. However, in case they want the facilities of the market yard, they have to pay a service charge, which should be sufficient to cover the operation costs of the market committee. It is therefore recommended that farmers, processor companies or other private operators may be allowed to operate their own wholesale market and charged a suitable fee for the service. This would encourage more investment in setting up infrastructures and create opportunities for providing better and more cost-effective services.

10. The reform of APMC would facilitate free movement of agriculture products between different States and from jurisdiction of one market committee to another. However, as market fee is a major source of income for a number of States, it may result in loss of revenue to some of them. It is felt that in the major cereal producing States like Punjab, Haryana, Western UP and Andhra Pradesh where bulk of food grains are procured by the FCI for the central pool, the loss of market fee may not be significant as the FCI and the State Government agencies are expected to continue their procurement through the existing Mandi structure. However, the mechanism of collection of market fees is widely being used to collect a number of add-on taxes, education cess, infrastructure cess, R & D cess etc., and alternate source of finance need to be formulated. Collection of all additional fees and cess in the market should be withdrawn and alternative sources of revenue should be found for
the same. In case the State Government feel that the abolition of market fees would lead to a loss of revenue, the rate of VAT on processors or semi-processors of agriculture produce can be increased suitable to compensate the loss of revenue for (e.g. by 0.5%). As of now, most of the horticultural products are already exempt from VAT.

**Budgetary Issues**

**Purchase Tax and VAT**

11. To create single market requires inter alia that there should be no customs barriers or measures having an equivalent effect at state borders or at borders within states. There are in principle two ways to fulfill this objective. One is to exempt agricultural products from indirect taxes. The other, which would be analogous to the one the EC has used, would be to change the administration of taxes so that no border measures would be needed.

12. Most of the physical barriers on primary agricultural commodities at State borders are on account of collection of sales/purchase tax or APMC cess or Octroi. Furthermore, verification of purchase tax return etc. is also another major function of these posts. The introduction of uniform rates of VAT in all the States and network connectivity between authorities where information regarding movement of goods from one VAT jurisdiction to another can be exchanged online may do it away with need for having physical barriers. The Government of India has stressed a lot on introduction of uniform VAT rate throughout the country and most States are agreeable. On processed and semi-processed agriculture products, it is recommended that a uniform rate of VAT should be applicable in all the States and that it should be collected at the first point of sale and retained by the State in which it is sold. If the product undergoes further value addition in the same State or on different State, VAT should be charged on the enhanced value and the VAT collected earlier would be rebated. This process could be facilitated by electronic exchange of information.

13. The limited experience of the States where VAT has been introduced has indeed been very positive as it resulted in a more transparent and efficient system of collection. Moreover tax collection itself has improved greatly in the States, which have introduced VAT. It is therefore likely that other States will follow suit and uniform VAT rate will prevail throughout the country before too long and the
government need to expedite the process. Most of the fiscal barriers on agricultural commodities would go in case the APMC be removed, and the check-posts of the market committees would also be redundant. Further removal of the documentation requirement would be extremely important for ensuring free flow of trade at the borders. It is recommended that the establishment of an electronic network for VAT may be expedited so that electronic exchange of information may substitute physical checking at the borders and would cut down a lot of documentation requirements. By VAT-ing taxes on the semi-processed products, there will be no need to check the produce at the borders.

14. The EU currently has dispensed with all border formalities without having reached the stage of full harmonization of indirect taxation. Instead of full harmonization, minimum rates of such taxes have been decided at EU level (e.g. for VAT the minimum rate is currently 15%) but member states remain free to set higher rates. In order to avoid trade distortions arising from these tax differences the principle has been established that products for sale in another member state are sent across the border free of tax and tax is then applied on sale at the rate applicable in the member state of sale. The one exception to this rule is that individuals are free to purchase products that are for their own use in another member state and bring them across the border without having any further tax to pay. The EU Commission regards this system as less than ideal, in particular because of the control problems arising from product being moved without have been taxed and has proposed fuller harmonizing but this proposal has not yet been adopted.

15. Abolishing indirect taxes on agricultural products is a policy that would not only resolve the problem of border taxes but would also be more socially equitable. As farm incomes lag behind average Indian incomes and the poorest sectors of non farm society spend the highest proportion of the income on food, indirect taxes applied to food products are doubly regressive. Furthermore, removing internal indirect taxes on agricultural products would tend to make Indian agricultural products more competitive on export markets. It is therefore recommended that Purchase tax or VAT should be exempted on primary agriculture products. It may be noted that a number of States are not collecting any purchase tax on primary
agriculture products. Moreover, State Governments have recently been empowered to exempt cereals and pulses from VAT.

16. The alternative would be to retain indirect taxes on agricultural products but not permit them to be collected or controlled at state borders. Purchase tax, for example, would be paid on first sale wherever first sale took place. Within this option, there is a choice between elaborate systems under which, if first sale took place outside the state of production, the collecting state would remit the proceeds to the State of production. Or the principle that the collecting states would retain the tax, which is the one that applies in the EC could be chosen. In either case, it would be desirable to unify the rate of tax, to avoid distortions under which operators would seek to make the first sale in the State with the lowest tax or, as a second best, to follow current EC practice and establish minimum tax rates that all States would agree to apply.

Octroi

17. As regards Octroi, it is well recognized that it is an onerous tax and the cost of collection is huge. More and more States have gradually abolished Octroi. However, it is an important source of revenue for the local bodies like Municipal corporations, which are often fund starved. Therefore it is suggested that if Octroi has to be continued as a revenue source, at least primary agriculture produce should be exempted from its coverage so that the farmers can be benefited.

Other Local Taxes

18. Some states have introduced certain other taxation measures, which impact agricultural products by impeding their movement and thereby adversely affect farmers’ income. It is recommended that they should be abolished. The measures like Himachal Pradesh Taxation (On Certain Goods Carried by Road) Act, 1999 are put in place in order to build up infrastructure by exploiting the frequently traded primary products. The same objective could be met by introducing indirect taxation policies (e.g. – by introducing an equivalent amount of cess on petrol so as to compensate the loss in revenue) in Himachal and other willing states. The indirect taxation introduced like this at least would create minimum distortion on the price received by the farmers.
Transport related issues

19. It has been observed that the reduction of the inter-state barriers might not lead to any direct benefit received by the farmers, given the prevailing cartelized nature of the transport industry. In order to translate the regulatory reforms undertaken into material gains received by the farmers (individuals as well as farmer cooperatives), the government must enact a definitive law against cartelization of the road transport industry.

20. In the EU the construction and maintenance of transport infrastructure is a national not a EU responsibility. But the contribution that transport links can make to regional development and the need to improve certain key intra Community transport links in order to create a Trans European transport network in the interests of improving the Single Market has been recognized. Therefore, member states may use some of the EU funds that are allocated to them under the EU’s regional policy, to part finance the construction of roads. And, as a means of improving the internal market, the Council and Parliament adopted in 1996 Community Guidelines covering roads, railways, waterways and traffic management systems in order to improve certain key connections. Under this, Directives have been addressed to member states in respect of key projects within this overall project and EU funding to cover part of the cost is being made available under a variety of legal instruments. India would do well to emulate the EU example in this respect.

Standardization and Harmonization of the Quality Standards

21. It has been mentioned earlier that the technical standards prevailing across the states are quite divergent and confusing at times. The prevailing scenario is also in a way responsible for the current level of lower internal trade. In addition, the regional confinement due to diversity of standards often does not allow the players to enjoy the economies of scale. Furthermore, in coming years organized retail is going to be very important in the country, and therefore there is an urgent need to ensure harmonization of the various prevailing standards across Indian states. Given the wide difference in the use of standards as well as selection of units prevailing in the country, the harmonization need to be introduced in every stage (e.g. – grading, packaging) to facilitate quick transaction. Apple is a fair example in this regard, where the level of standardization in the country is quite comprehensive, explaining the
intensity of inter-state trade in it all over the country. The Food Safety and Standards Bill (2005) is a welcome step by the Government, which will ensure the desired harmonisation as it would supersede the State laws, once enacted.

22. Harmonization of standards removed many non-tariff barriers in the EU. If, when the Food Safety and Standards Bill in India have been enacted, it emerges that there remain some state standards that differ from national standards then the principle of mutual recognition that applies in the EU in areas where there is no EU wide standard could be applied. Under this principle, whilst member states can establish their own standards in cases where there is no EU wide standard, they are not permitted to prevent the sale on their market of products that meet the standards applied in another member state.

23. The absence of common grading standards can also act as a form of non-tariff barrier even if it is not compulsory to use the standards applicable in the state of sale, because the absence of standards inhibits direct sales from producers to distant markets, because as such standards are needed to allow contracts to be entered into without prior sight of the products. Again the Food Safety and Standards Bill should help to address this issue.

24. In India the Bureau of Indian Standards (BIS) and AGMARK are there but the level of enforceability varies widely across states. Indian standards are formulated through participation from various stakeholders, including representatives from the government, consumers and industry. The standards are laid for various categories like vegetable and fruit products, spices and condiments, animal products and processed foods etc., and product quality is checked through either ISI laboratories at Delhi, Bombay, Calcutta, Madras, Chandigarh and Patna or in a number of public and private laboratories recognized by them. On the other hand, the AGMARK ‘seal’ provided by AGMARK standard, set up by the Directorate of Marketing and Inspection of the Government of India in 1937, ensures quality and purity of a product. The government should utilize both these provisions for ensuring harmonization across the country, apart from the provisions of Food Safety and Standards Bill (2005). While ISI certification is purely voluntary, AGMARK seal has been made mandatory for only a few products. As a result, a large number of products are brought to market without standardization. Moreover, there is no compulsory
standard packaging requirement except for edible oils and vanaspati. More products should be brought under the ambit of AGMARK and that even packaging should be standardized. The fluidity and transparency of a Single market would be further enhanced if grading standard for food process, particularly horticultural products, were established on an India wide basis.

Non-Regulatory Issues

Policy Support for Creation of Farmer-Centric Environment

25. The gain from removing indirect taxes or savings in transaction costs as described earlier would initially benefit traders and the transport industry. Both are areas where competition is limited, by the accreditation system that limits free entry into the trading sector and by the agreement that exists between truck owners. It is difficult to ascertain whether these limitations on competition in fact raise the charges they make above the cost of providing their services but, to ensure that the savings arising from the removal of border checks were transmitted back to growers and on to consumers, it would be desirable to increase competition, by freeing up access to the trading sector and forbidding restrictive agreements in the transport sector. The realization of the benefits of market integration to benefit small farmers depends on the measures to address supply side constraints, which prevent this category of farmers to take advantage of the opportunities opened up by greater market access, and help them to increase competitiveness or diversify. Some of these issues are examined below.

Formation of Producer Organizations

26. The economies of scale in procurement, technology adoption and marketing are better attained if small farmers combine together as producers groups. From the supply side it is not easy for value addition enterprises to work with a large number of small farmers, which involve problems of product uniformity, product traceability and variation in cropping programs leading to a greater management input and raw material procurement cost. In a number of countries Governments also encourage small farmer involvement in agro-enterprises. The motivation for the enterprises comes from government offering tax breaks and concessions, a supporting bureaucracy or relaxing zoning laws when companies are establishing new processing units or retail outlets, Government support services related to strategic crop
production, specialization etc. Consequently, the small farmer gains access to the market, the consumer welfare increases substantially, and the processors and pack houses have a focal point, for example, a producer group or association to work with.

27. The farmers group operation would facilitate export requirements for quality and traceability, which is currently not always possible with numerous smallholdings. In farmer communities, due diligence will be accorded through proper record keeping and monitoring on the farm during the production process and with strong linkages within the supply chain.

28. The formation of farmers’ organizations would further facilitate crop specialization in clusters. Farmers in specific agro-climatic zones with comparative advantage for certain crops or products can obtain a comparative and competitive advantage by crop specialization in conjunction with other farmers in the location. Already there are areas in the country that have a reputation for growing certain types of horticulture crops - Nasik for grapes and onions, Nagpur for mandarins, Nawasari for chikoos, Durg for papaya, Kullu for apples, the Kashmir Valley for saffron and Hoshiarpur for kinnaw. The three main reasons for specialization are; (i) the limited and finite resources in the area can be channeled to work with the farmer groups on those crops or products; (ii) processors and industry will become concentrated and established in the production zone, if the region can provide sufficient volumes of product and continuity of supply to make a processing enterprise viable; and (iii) farmers can manage a particular crop or a group of crops in order to achieve specialization.

29. The proposed producer companies’ enterprises could take various forms, e.g. - agricultural cooperatives etc. The agricultural cooperatives in India have so far suffered from various institutional drawbacks (poor management quality, absence of the right decision-making capability, excessive government control etc.) and are moderately successful. The government should provide start-up capital to these producer enterprises through institutional support policy (credit in easy terms) as well as technical support (opening training centres to provide management skills to the village-level select representatives from the cooperatives) to avoid the potential problems. National Dairy Development Board being the best example of the success story. The Company Law has been recently amended to permit formation of producer
companies, which have certain tax and other advantages. This form could be well suited to form strong farmer enterprises.

**Credit Policy**

30. One of the major goals of the study is to recommend suitable policy frameworks towards creation of a common agricultural market. While the need for extending the credit net for enhancing agricultural growth has been well known, its necessity for creation of the common market is also quite obvious. The driving motive behind the creation of the common market is to increase the return to the farmers through enhanced internal trade in agriculture and increase in agricultural production as well as the productivity is a pre-requisite for that. Given the resource-constraint of the average Indian farmers, it is unlikely that they would be able to increase investment in land or productivity on their own. In that case, the gains from the creation of the common market would bypass a major segment of the farming community, and the whole purpose would be defeated. Therefore, the government needs to formulate a much stronger and wider credit policy, working in the interest of the small and the marginal farmers.

31. While the current government credit policy is already focusing on extending the facilities to the small farmers, there is an urgent need to the broad base it further. It will not be possible for the government to help the formation of producer enterprises all over the country in one go. While the formation of producer enterprises could be encouraged in some select areas (where specialization is readily possible) initially through financial and technical support, access to credit could be extended to the uncovered regions both directly as well as indirectly. A significant proportion of the farmers is not covered by the official credit net, and has to go to the moneylenders or arthiyas for credit. The regional rural banks need to be energized to solve this problem. Secondly, having a vibrant private sector would indirectly contribute in this regard as they have already started providing credit to the farmers selling their product to them in the form of quality farm inputs. Removing the remaining barriers for private sector operation would facilitate this trend further.
Provision of Market Information
32. It has been noted earlier that absence of market information (both on prices and appropriate post-harvest measures) acts as a major negative force on Indian farmers. It is the responsibility of the Government to provide the timely information especially to the small and medium farmers. The current level of Government effort remains mostly inaccessible by these groups at large. The Private sector initiatives like the e-choupal model of the ITC and the innovative marketing strategies of several other private players are successfully supplementing the Government initiatives and appropriate policy measures must be undertaken in order to encourage these types of arrangements. The proposed reform of the AMPC Act would be a major step in facilitating the entry of more private players in this sector. The optimality of the operation of private players have already been reflected through higher price to the farmers and increased productivity.

Creation of Rural Infrastructure
33. In order to create a common market, creating a minimum level of infrastructure connectivity is necessary. Infrastructure services such as roads, electricity supply and telecommunication and others are limited in rural areas. Warehouses, cold storages and post-harvest practices are awfully inadequate. As private investors are generally shy in investing in such infrastructure which is more in the nature of public good, government must continue to be the major investor in creating rural infrastructure. A recent study undertaken on behalf of IFPRI on “Linkages between Government Spending, Growth and Poverty in Rural India” found that for each Rs. 10 Lakh spend on roads, 165 people will be lifted above the poverty line. Rs. 10,000 crores are spent on roads will increase productivity growth by more than 3 percent as well as increase in non-agricultural employment.

34. Ongoing projects like “Bharat Nirman” will certainly help in achieving the objectives. Apart from enhancing the government support to the agricultural sector, the private sector has to be encouraged to invest more in the infrastructure building, as the state participation is clearly less than satisfactory. There is a need to adopt various innovative projects to enhance public-private partnership to build adequate infrastructure, both marketing as well as physical, for the primary sector.
To attract promoting agencies to take up infrastructure projects, the Central / State Governments need to additionally extend support in the allocation of suitable land to set up the market, provisions of village land for farmers’ association and collection centres, deregulation of area from the APMC Act where new markets were to set up, ensure first approval of foreign technical assistance, import of equipment and services like electricity, service, sewage, telephones etc.”

35. The disguised unemployment in Indian agriculture is a major problem, and transfer of the surplus labours to other economic activities is a major challenge to the government. Although extension of labour intensive horticulture is capable of absorbing a proportion of the excess labour employed in traditional agriculture, there are limits to diversification and promoting off farm opportunities is quite important. Apart from focusing on ‘Bharat Nirman’, the government needs to concentrate on ‘PURA’, which plan to enhance physical, electronic and knowledge connectivity of the villages, with significant positive externality on agriculture sector.

36. Apart from strengthening the road network, attention also needs to be paid to the mode of transportation of agricultural produce. Railways are an efficient means of transport of goods over long distances, but most railway wagons in India are not designed to carry agricultural and food products in bulk. Products have to be generally transported in gunny bags in open or closed wagons, which do not have any facility for mechanical loading or unloading. Silo storage or bulk handling and movement is rarely undertaken. Cost of transportation could be greatly reduced if suitable steps are taken for bulk handling for agricultural produce by trains. There is also a need to increase availability of refrigerated vans for carriage of fresh farm produce, which are highly perishable, this would minimize travel and transit losses and be time and cost efficient.

37. Another cost-effective means of transport would be to encourage internal trade in agriculture through inland waterways. There is an extensive network of rivers and canals in the country and most of the productive regions are adjacent to them. However, unlike in Europe, China and many other countries in the world, inland waterways are rarely used in India to transport bulk commodities. In fact, over time most of the waterways have gone into disuse. They need to be revamped by regular ridging, if necessary. One additional benefit of introducing this would be a favourable impact on environmental pollution.
CHAPTER IV
TECHNOLOGY MISSIONS: WAY FORWARD

4.1  Historical Backdrop

4.1.1  Technology Mission as a technique or a method to achieve specific development goals was initiated in 1986 by the former Prime Minister late Shri Rajiv Gandhi. Five Technology Missions were initiated, out of which Technology Mission on Oilseeds was one. In his Convocation Address at the IARI, New Delhi in February, 1986. Late Shri Gandhi said - “One of our biggest problems today in the agricultural sector is the oilseeds. We are setting a thrust Mission for oilseed production. When we talk of a Mission we mean an exercise starting from engineering of the seeds and, finishing with the finished products of the vegetable oil, which could be delivered to consumer. We would like to put of one person in-charge of such a mission with full funding with no restriction on him whether bureaucratic or otherwise. The only limits will be certain achievements, which must come within a certain time frame. This will cut across a number of Ministries where you find a lot of hassles and we find our projects getting stalled because the interaction is not smooth enough. We have already decided on this particular Mission ………”.

4.1.2  Till the 1980s, programmes for enhancing the production and productivity of various agricultural crops was sought to be achieved through investment in inputs and provisions of subsidies to farmers through specific programmes along with investment in infrastructure like major and minor irrigation etc. However, with the ascent of Shri Rajiv Gandhi as Prime Minister of India, it was felt that new approaches and methodologies were necessary to give the required fillip to various crops, particularly those which were items of mass consumption and whose shortage led to large import bills. Fortunately, this was the stage when the importance of technology driven growth in agriculture was realized more clearly. It was also the time when the problems of coordination in meeting the felt needs of the farmers and the need for an end to end approach towards growth of production and productivity was also realized. The 80s also saw the arrival of Dr. Sam Pitroda with his reputation in the field of science and technology and his known capacity to cut through the traditional methods of governance, for leading the Technology Missions.
4.1.3 These developments at the Centre were matched by substantial enthusiasm in the States because of the enthusiasm and vision of Shri Rajiv Gandhi in the context of his very large political mandate and the zeal of Dr. Sam Pitroda in converting the States into new thinking for rejuvenating agriculture.

4.1.4 The 80s therefore saw the congruence of several positive factors when the Technology Missions were born. The Centre had formulated a new methodology to ensure significant technology inputs and more efficient delivery mechanism for optimising yields of crops and the States were equally enthusiastic in implementing the ideas in order to gain political mileage and also benefit farmers in drylands.

4.1.5 The following key elements of the Technology Mission approach emerged:

(i) Effective transmission of available technology even while encouraging research on newer technologies.

(ii) An end-to-end approach in order to meet all the requirements of the farmers in an integrated way.

(iii) An effective integration of the activities of various Stakeholder Departments so that the needs of the farmers could be understood comprehensively rather than through segmented lenses.

(iv) Crops where there was a significant gap between the actual and possible productivity mainly due to insufficient/ inappropriate transmission of technology to the fields.

4.1.6 Briefly, the Technology Missions were designed to be technology rich and to comprehensively transfer the available technology enhance profitability and incomes of farmers through appropriate attention to both production and post-harvest and processing issues. This was expected to be achieved through full collaboration between the Centre and the States and collaboration amongst various departments involved.

4.1.7 These Missions were also supposed to be driven by dynamic and knowledgeable missions Directors who had the capacity to comprehend the technology as well as the delivery systems and who had the vision to deliver results in
a time bound manner. Last but not the least the Technology Missions were expected to be backed by appropriate policy support in order to protect the incomes of farmers. With this historical background, the formulation and implementation of the discontinued as well as ongoing Technology Missions in the Agriculture Sector are being analysed.

4.2 Technology Mission on Oil-Seeds and Pulses (TMOP)

4.2.1 Between 1981-85, the area under oilseeds was fluctuating between 18-20 million hectares, production between 9-12.9 million tonnes and productivity between 563-684 kgs per hectares. The percentage of area under oilseeds, which received irrigation, was less than 14-17%. The soils in which oilseed crops were cultivated were mostly hungry and thirsty because the resource poor farmers particularly under dryland conditions were not able to provide the needed inputs of fertilizers, water or plant protection. The erratic monsoons further put the oilseed production at risk. There was no well-developed technology and high yielding varieties like in wheat and rice to push up the oil-seed production. Most of the oilseed crop varieties were susceptible to a large number of pests and diseases and they were also affected by abiotic stresses like drought, salinity, alkalinity etc., Devious market forces also dampened the enthusiasm of the farmers to go for oilseed cultivation. The efforts that had been made earlier through research and development activities had not increased production to any appreciable extent while the growing population and industrial needs of the vegetable oils, both edible, and non-edible had been steadily going up. To meet the growing demands India had to resort to import of edible oil which reached 1.6 million tonnes costing Rs.1319 crores in 1983-84 and 1.4 million tonnes costing Rs.1122 crores in 1984-85. This was a huge drain on foreign exchange resources of the country and if it was not controlled through proper strategies to step up the production of domestic vegetable oilseeds import of oils could reach an estimated Rs.3000 crores by 2000 AD. The major edible field oilseed crops of the country were groundnut, rapeseed-mustard, sesame, safflower and niger and among the non-edible castor and linseed. Area under soybean and sunflower was limited and coconut oil consumption was localized. In this background, the Technology Mission on Oilseeds was expected to achieve the goal of self-sufficiency in a stipulated time frame.
4.2.2 A SWOT analysis revealed that we had the strength of soils, climate, research and developmental infrastructure to grow horizontally and vertically by encouraging oilseed crop cultivation and also by use of need-based necessary inputs. Since the soil and climatic conditions of the country were very diverse, a number of oilseed crops could be grown which was not the case in most of the countries around the globe. The yield gap was a great opportunity to exploit. The well laid out demonstrations by the scientists on farmers’ fields by use of available knowledge and technology had brought out clearly the possibility to raise the yield significantly. Besides, this opportunity there was a well-developed developmental infrastructure of Departments of Agriculture, Forestry, Scientific Institutions, input agencies and industry in the country. The major threat was the import of cheap vegetable oil from abroad without proper checks and balances that dampened the initiatives of the local farmers.

4.2.3 The target to raise the present oil seed production from 12.4 to 26.0 million tonnes and vegetable oil production from 3.6 to 8.0 million tonnes by 2000 A.D. was fixed as the goal of the Mission.

4.2.4 **Strategy Development:** To bring a new vigour into the vegetable oil scenario, several steps were taken. Intensive discussions between scientists of ICAR and administrators of Department of Agriculture and Cooperation (DAC) Government of India were taken up to take stock of the existing scenario and explore opportunities to step up oilseed production. This was followed up with interactions with the officials of the Commerce and Civil supplies Departments on supply-demand scenario, with the scientists of Council of Scientific and Industrial Research, on technological options on improving the efficiency of oil extraction and organizations and departments that fix the prices of the different oilseed crops. Based on these deliberations at the Central level, similar interactions were organized at the level of different important oilseed crop growing States of the country.

4.2.5 Based on all these intensive discussions and keeping the critical role of the farmers who grew the oilseed crops for bettering their income, four MMs (MM) covering all the activities of the oilseed scenario in totality were started both at the
Central and State level and to impart momentum to the Mission. These four MMs were:

- MM I – Dealing with crop technology
- MM II – Farmer support system
- MM III – Price support, processing, storage and marketing
- MM IV – Post harvest and processing technology.

MMs I and IV where technology is involved, were to be operated by DARE and CSIR respectively and Missions II and III were to be looked after by DAC.

4.2.6 The leaders for these MMs were identified both at the Central and State levels. Seventeen different agencies were involved in the various activities dealing with vegetable oil scenario. To coordinate, facilitate and execute the different activities and programmes, a full time Mission Director was appointed. The Technology Mission on Oilseeds recognized at the very outset the critical role of technology in production and processing and coordinated and integrated action, with follow up. The participatory role of all the agencies and farmers was also fully realized and a bottom up rather than a top-down approach was followed. Incentive prices for each of the oilseed crops were announced from time to time to enthuse the farmers. The National Agricultural Research System involving ICAR, State Agricultural Universities, Central Commodity Boards, private industry, Oilseed Federations, CGIAR, CSIR, ICMR and other scientific institutions, development departments/ministries/agencies were all brought together and all of them identified themselves as partners in achieving the objectives of the Mission. This cooperative, coordinated approach with a sense of ownership and commitment by all partners was one of the reasons for the success of the Technology Mission on oilseeds.

4.2.7 The Technology Mission on Oilseeds launched in May 1986, drew up the following strategic plans after due deliberations:

1. Identification of crops/States/areas, which have the highest potential for increasing production.
2. Development of short term and long term plans.
3. Identification of institutions and leaders at every level who will implement the plans and programmes.
4. Organisation of field demonstrations on a massive scale with available technologies and sensitise farmers and extension workers.

5. Documentation of all the strategies with cooperation of scientists/administrators/policy makers at the Central and State levels.

6. Development of activity milestones, time frame and implementation and review methodologies.

7. Constant and frequent reviews by the Mission Director and mid term course corrections where and whenever needed.

8. Mission activities to be reviewed once in three months by the high powered Steering Committee headed by the Secretary, Agriculture and Cooperation and Secretary, DARE with all the MM leaders and the Mission Director. Reporting to the PMO on a regular basis about the progress.

9. Organisation of national seminars and States level seminars, regional workshops involving scientists, industry, policy makers etc., and organizing training programmes.

11. A very objective and result giving strategy laid out and followed which gave good results was:
   a. Identifying crops, technologies and areas that could be exploited for increasing production, productivity and extractability of oil at the shortest possible time
   b. Identification of non-traditional areas of the country where the crops could be introduced and exploited
   c. Introducing non-traditional crops on a large scale
   d. Improving the oil extraction technologies in different mills
   e. Exploitation of rice bran and cotton seed as a source of oil and
   f. Exploitation of tree species of forest origin.

12. In the strategy, high importance was given to –
   a. Rabi groundnut production
   b. Promoting rapeseed-mustard in a big way in Rajasthan and non-traditional areas like Central, South and East India
   c. Extending area of cultivation and intensifying production and processing technologies of soybean
d. Import of seed of high yielding varieties/hybrids of sunflower and popularising it  
e. Introduction of high yielding tenera hybrid plant material of oil palm  
f. Import of rice bran technologies from USA/North Korea  
g. Improving solvent and other rice bran technologies  
h. Announcing remunerative prices  
i. Extension of existing knowledge and development of new knowledge  
j. Extraction of oil from cotton seed and maize  
k. Blending, package and storage technologies  
l. Strong support of DAC by developing National Oilseed Development Programme (NODP)  
m. Gradually reducing the import of oils

The above strategies based on scientific analysis gave significant boost to oilseed production and reduced the import bill. An attempt was also made to look at alternate crops like Simarouba glauca, Pongamia, Sal, Mahua and other tree species for meeting the needs of both edible and non-edible oils.

4.2.8 As a result of the thrust given by the Government of India, the Technology Mission on Oilseeds (TMOP) achieved the goals of increasing domestic production and reducing the dependence on imported oil.

(i) Between 1985-86 and 1998-99 the production of oilseeds increased from 10.83 to 24.75 million tonnes, yield per hectare increased from 570 to 944 kgs. and the area under oilseed crops increased from 19.02 to 26.23 million hectares.

(ii) The strategy of non-traditional areas and non-traditional crops paid rich dividends.

(iii) The thrust given to rabi groundnut, soybean, rapeseed-mustard, sunflower, oil palm paid well.

(iv) The solvent extraction technologies, the conversion of hullers to shellers and rice bran extraction technologies gave good results.

(v) By 1992-93, the import bill on vegetable oils came down very significantly.
4.2.9 Addition of Pulses
